NeurAbilities Healthcare

The Child Neurology Foundation mission is to serve as a collaborative center of education, resources, and support for children and their families living with neurologic conditions, and facilitate connection with medical professionals who care for them

Shortening the Diagnostic Odyssey Matters

- Average length of time from symptom onset to an accurate diagnosis of a rare disease is 5 years (1)
- 80% of rare diseases are caused by a faulty gene (2)
- 90 % of rare childhood disorders have major neurologic effects (3)

(1) Engel PA, et al. Physician and patient perceptions regarding physician training in rare diseases. Journal of Rare Disorders 2013: Vol. 1, Issue 2.
(2) Bavisetty S, et al. Emergence of pediatric rare diseases. Rare Diseases 2013, volume 1.
(3) National Institute of Neurological Disorders and Stroke (NINDS) Strategic Plan 2021- 2026

Shortening the Diagnostic Odyssey Matters

- A third of child neurologists report over 25% of their patients are undiagnosed
- 35-50% of families are still looking at 3+ years for a diagnosis
- 44% of caregivers have had to deal with a misdiagnosis

SOURCE: CNF 2021 CHILD NEUROLOGIST AND CAREGIVER NEEDS ASSESSMENTS

Putting it all together

Last year we discussed
how to facilitate and shorten the odyssey

This year we discuss
what to do when all the testing is done

Today's Agenda

- How a Whole Genome Sequencing Opportunity Impacted 25 Children, Caregivers and their Medical Providers
- Getting from Gene to Treatment and Disease-Specific Clinical Trials
- Possibilities with N-of-1 trials
- Participant Reflections and Break
- How to handle the various journeys
- Panel Discussion: How to effectively collaborate to get answers

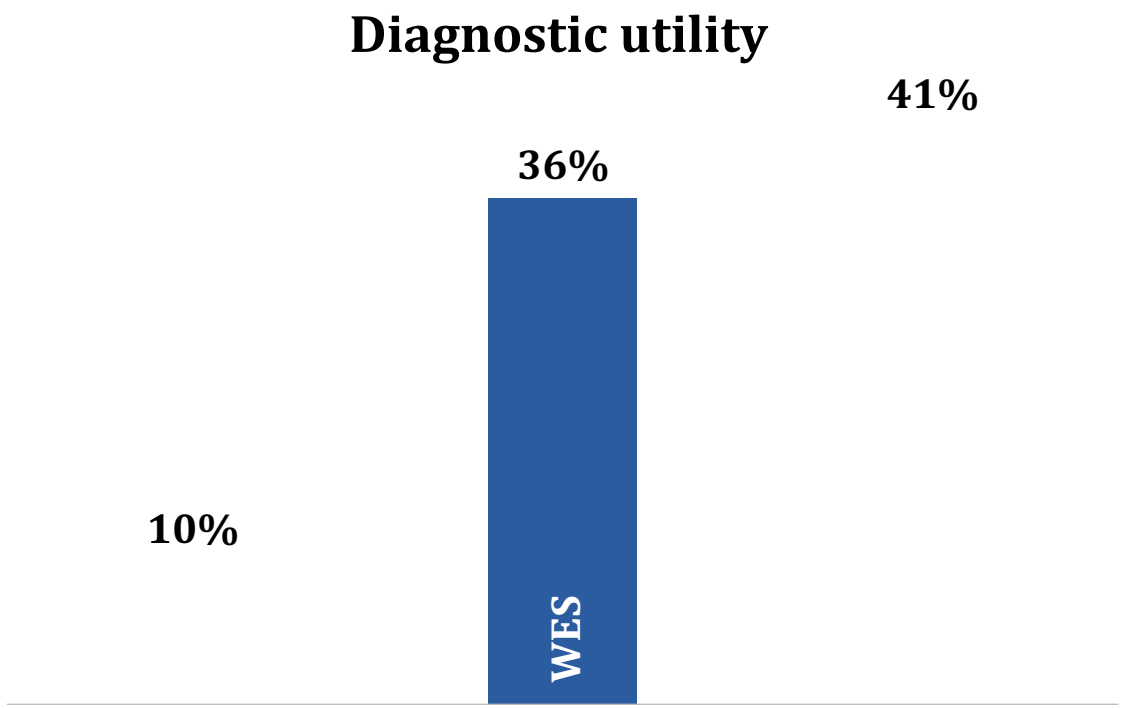
WGS and WES Offer Significant Improvements in Diagnostic Success vs CMA in Select Patient Groups

8.3X GREATER ODDS OF DIAGNOSIS with WGS/WES*

In a meta-analysis of literature from January 2011 to August 2017, 37 studies comprising 20,068 children were included for review of diagnostic utility of 3 testing approaches: CMA, WES, and WGS



*95% CI: 4.7-14.9, *P*<0.0001.

CMA=chromosomal microarray; WES=whole-exome sequencing; WGS=whole-genome sequencing.

Highlights from ACMG Guideline

Exome and genome sequencing (ES/GS) for pediatric patients with congenital anomalies or ID/DD

- Strong recommendation for ES/GS as a first- or second-tier
- There is evidence of clinical utility of ES/GS in these indications
- Feasibility and acceptance of ES/GS have been demonstrated by relevant stakeholders

Manickam, K., McClain, et al. Exome and genome sequencing for pediatric patients with congenital anomalies or intellectual disability: an evidence-based clinical guideline of the American College of Medical Genetics and Genomics (ACMG).. Genet Med (2021) https://doi.org/10.1038/s41436-021-01242-6

CNF's WGS Program

39 Site Applications (104 Cases)

5 Sites Selected

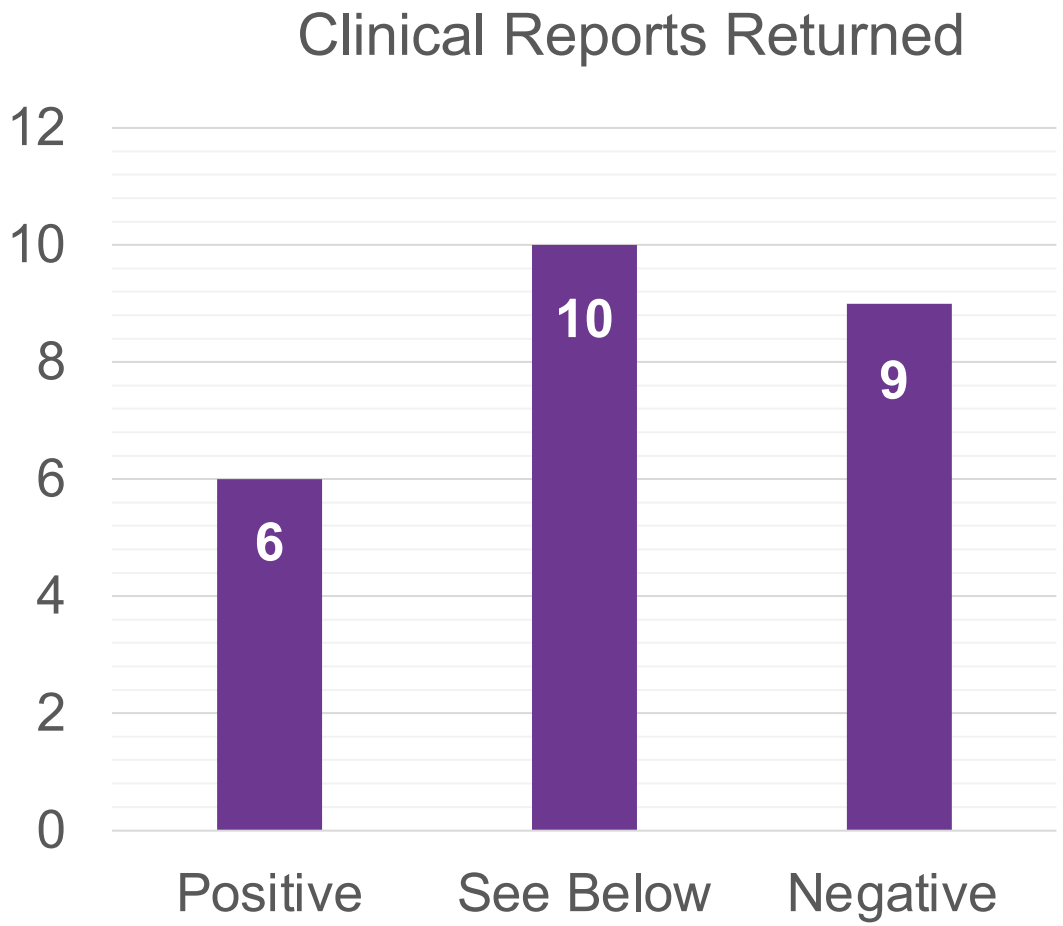
25 Children Received WGS at **no cost**

Thanks to the generous support of Illumina

Application Review Process

- **Applications accepted**
  - Mostly academic institutions applied
  - Did not have WGS available even for research purposes
- **Cases reviewed independently by two neurology providers**
- **Cases selected based on possibility of**
  - Diagnosis given previous genetic results
  - Potential treatment implications
  - Significant co-morbidities

Reporting Details



24% of Children Received a Diagnosis

Report labels

- **Positive**
  - Clinically significant (LP/P) variant in a gene with a gene-disease relationship that is at least moderate as based on the ClinGen Framework (PMID: 28552198)
- **See Below**
  - All VUS variants regardless of gene-disease relationship classification
  - Incidental findings
- **Negative**
  - No variants reported

Aggregate Data from Illumina Clinical Services Laboratory; Sarah Schmidt M.S. and Rady Children's Institute, Lisa M. Salz, MS, LCGC

5-year search ends with new care plan and connection

- Hiccups and jerking movements felt in utero
- Frequent myoclonic movement and hypotonia noted in infancy
- EEG showed encephalopathic pattern
- Unique facial features and VSD noted
- Extensive work-up (MRI, metabolic, genetic) unremarkable
- Diagnosed with a movement disorder and other chronic medical issues
- QWGS found diagnosis of PURA syndrome which brought relief and connection to support/advocacy group

14-year search ends with tailored prognosis and improved family planning

History of leukoencephalopathy, mild ID, spastic diplegia, short stature, progression sensorineural hearing loss, and retinitis pigmentosa

Repeat brain MRI showed progressive white matter lesions

Other work-up non-diagnostic

Two trio exomes 2013 and 2019 (separate labs) both non-diagnostic

WGS testing showed pathogenic variation in MORC2

Closure for family and relief

Closure for Family

- History of developmental epileptic encephalopathy
- Treatment resistant epilepsy
- Other work-up non-diagnostic
- WGS testing showed pathogenic variation in TATA-box binding protein associated factor 1 (TAF-1) gene
- X-linked recessive
- Mother asymptomatic carrier

“Families that didn’t get a diagnosis were not surprised; they have already done a lot of testing with no answers. They were grateful for the opportunity.”

“For the family with a diagnosis, having the answer was very positive, even though it was rare and there is currently no treatment.”

“Families are interested in the testing, and it can change care in meaningful ways such as giving them opportunities to connect with other families and to engage in research efforts.”

“WGS changed the child’s prognosis. We suspected a mitochondrial disorder, so he was getting a mitochondrial cocktail. His diagnosis is not mitochondrial, though still rare and some limits on prognosis, but it is better. It is non inherited, so the parents don’t have to worry about their other child and can plan for future children as well.”

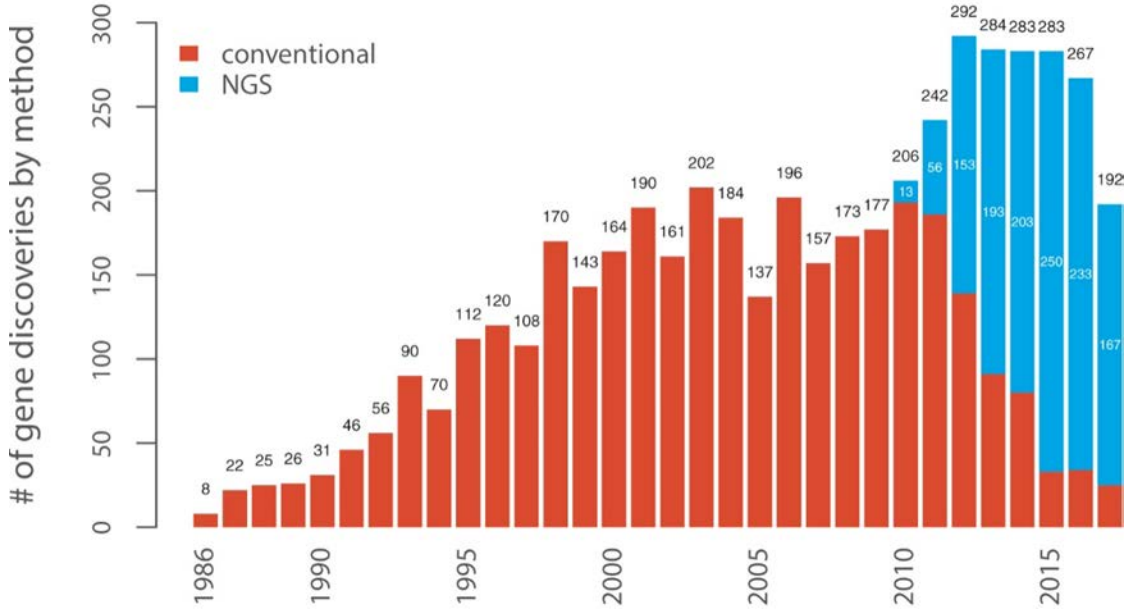
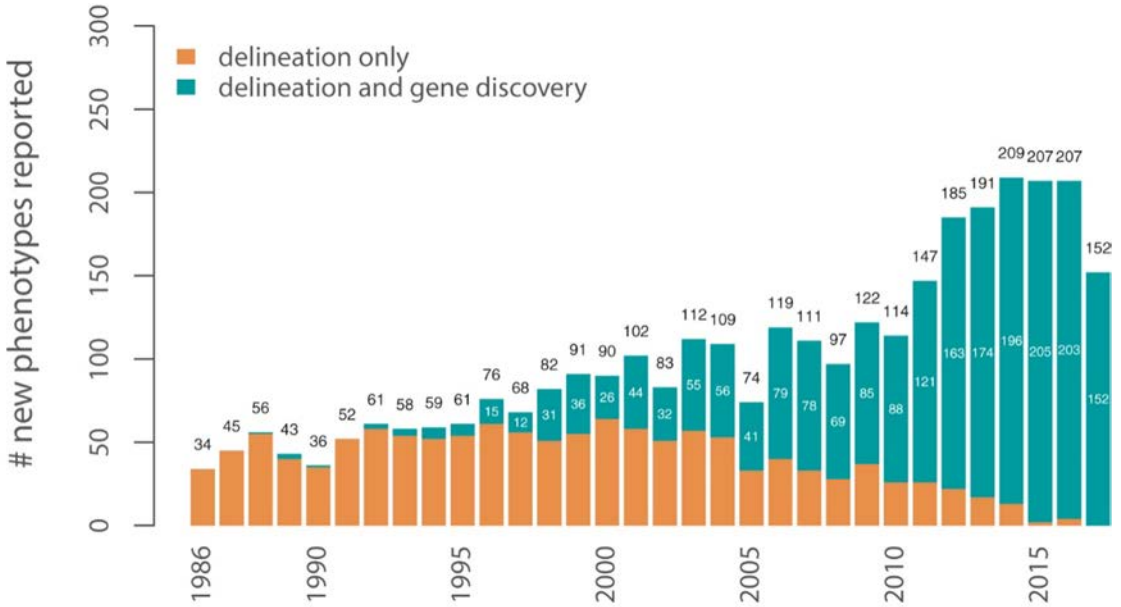
Objectives

- To understand factors that are enabling rapid advancement in development of novel therapies for orphan conditions
- To understand key importance of preparatory research to enable efficient and informative trials

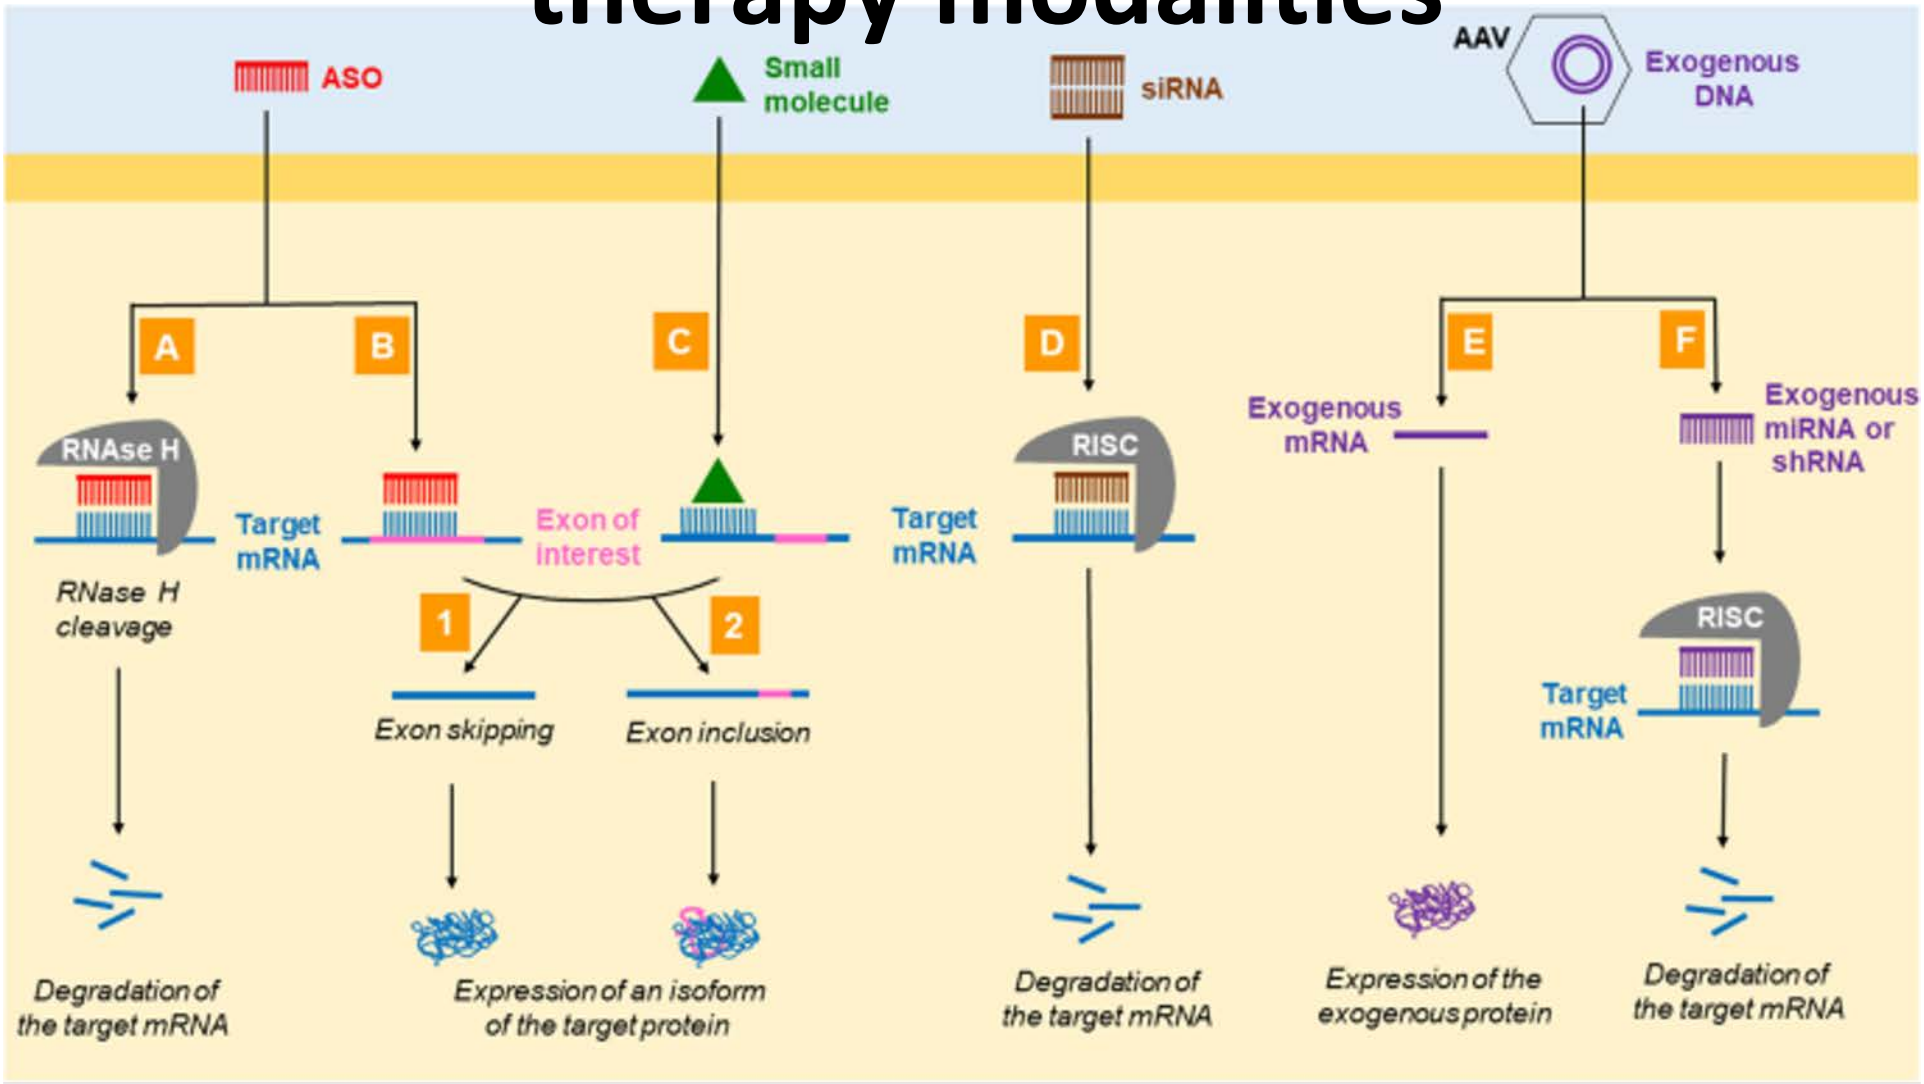
Rates of gene discovery and syndrome delineation are increasing





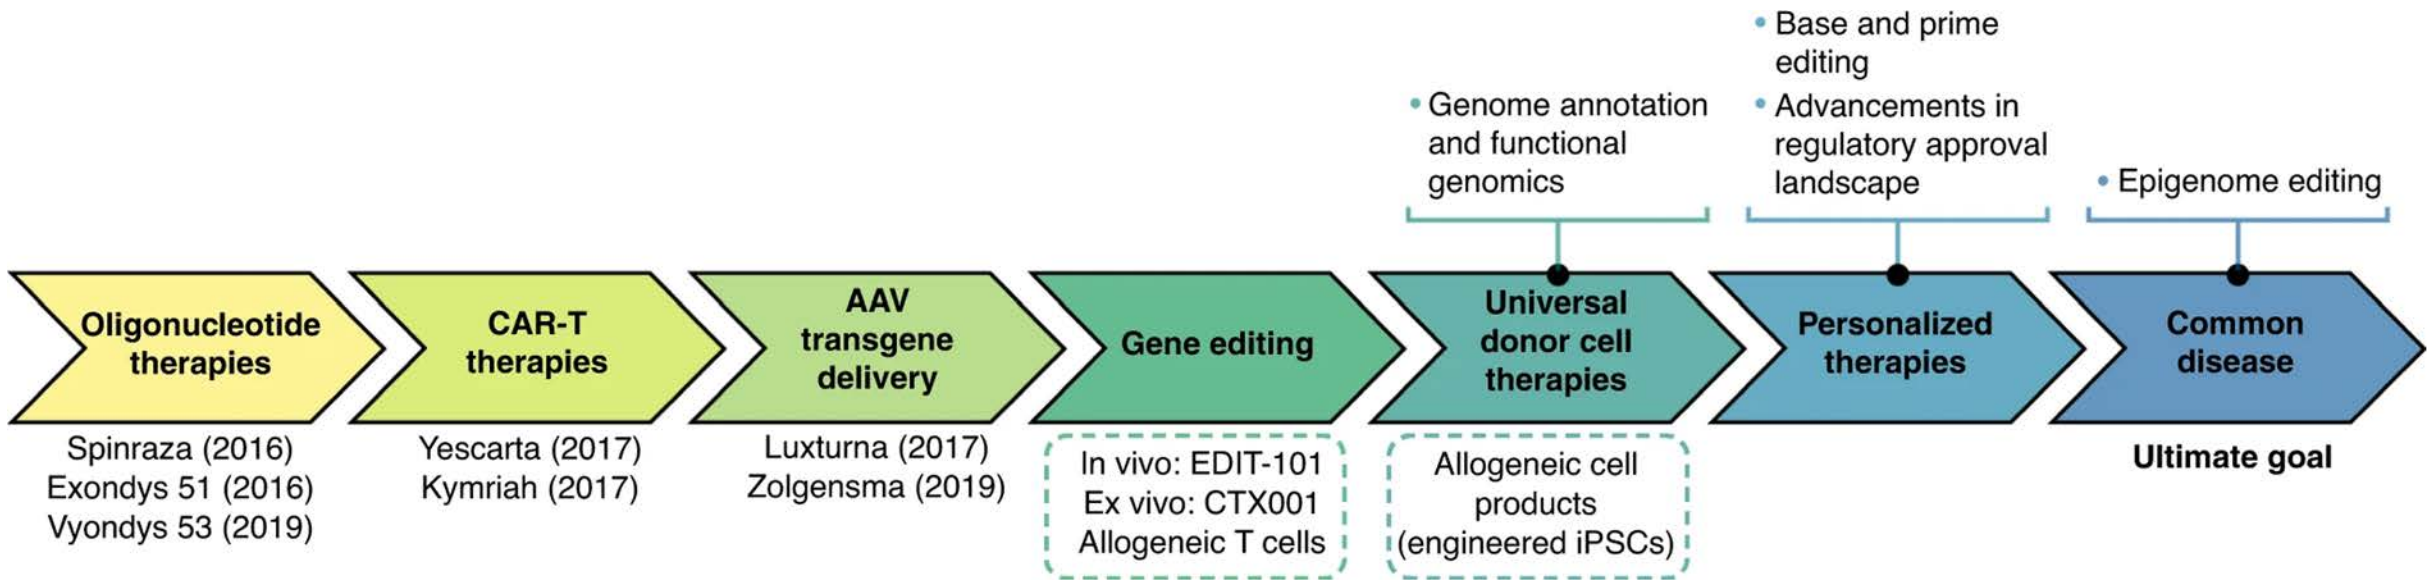
AJHG. 2019; 105: 448–455.

There are a growing number of gene-targeted therapy modalities



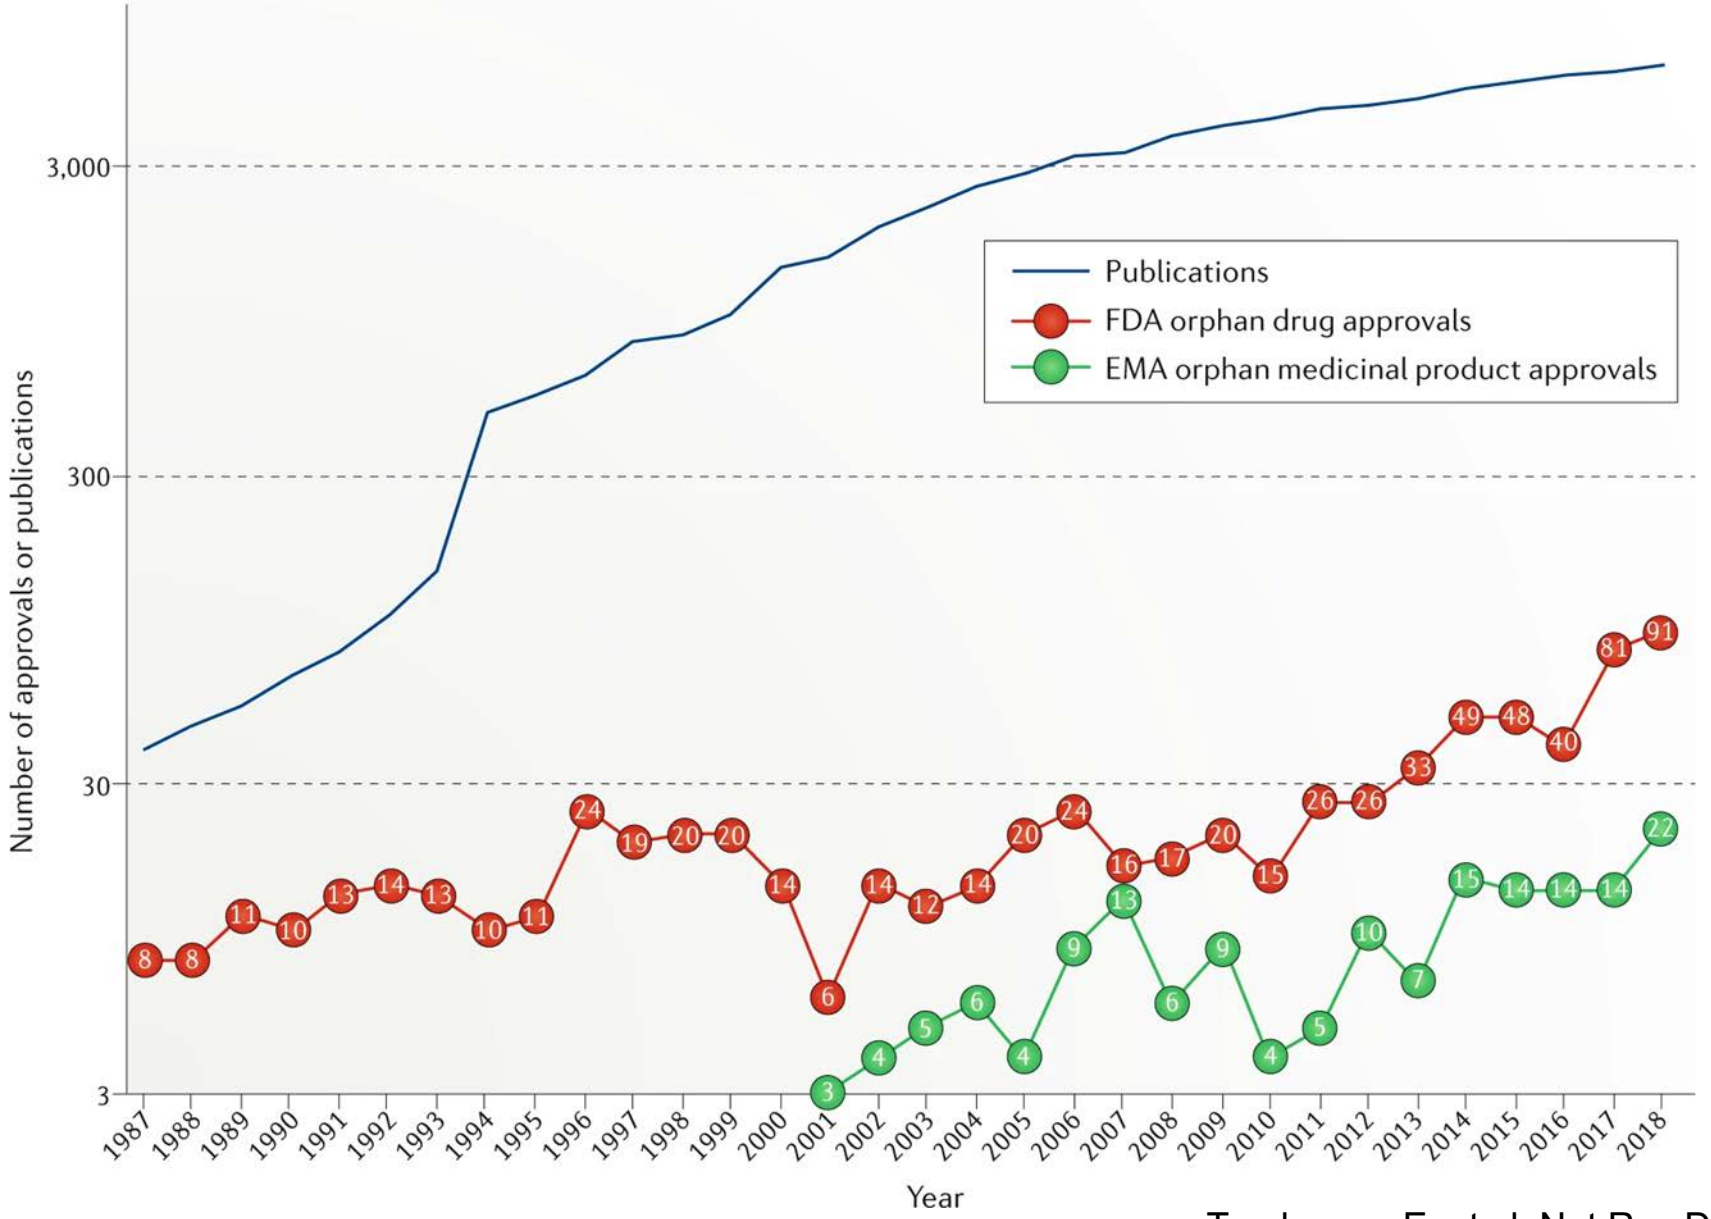
Brenner et al. Neurological Research & Practice. 2020; 2:25.

Milestones in the development of gene-targeted therapies



K Bulaklak, et al. Nat Commun. 2020; 11: 5820.

A translational gap remains and is widening



Tambuyzer E, et al. Nat Rev Drug Discov. 2020;19(2):93-111

Gene Discovery

Gene Targeted Therapy

Gene Discovery

Gene-Targeted Therapy

Pre-clinical Discovery

- Understand disease mechanisms
- Generate animal models that recapitulate human disease
- Identify therapeutic targets
- Processes of drug discovery
  - Compound screening/construct development
  - In vitro, in vivo analyses
    - Proof-of concept
    - Dose, safety, toxicity, efficacy

Gene Discovery

Gene-Targeted Therapy

Clinical Trial Readiness

- Understand natural history
- Identify important impacts for families
- Establish robust outcome measures & potential endpoints
- Biomarker development
- Identify experienced investigators
- Mobilize community

Gene Discovery

Gene-Targeted Therapy

Clinical Trials

- Adequate and appropriate trial design
- Consultation with regulatory authorities
- Strong community engagement
- Clinical trial programs that address a series of development questions
  - Safety
  - Dosing & route of administration
  - Target population & time of intervention
  - Efficacy

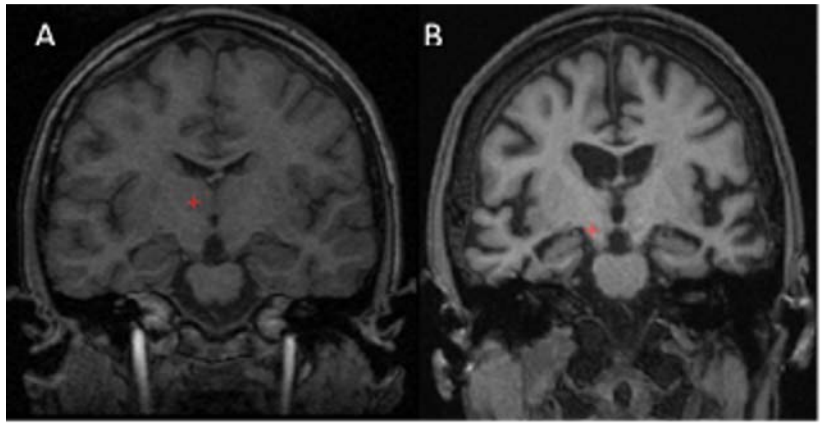
Gene Discovery

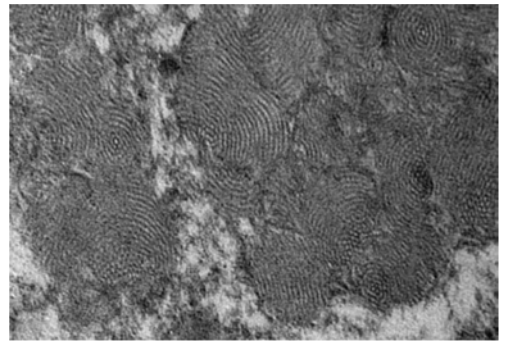
Gene-Targeted Therapy

Clinical Trial Readiness

Neuronal Ceroid Lipofuscinoses

- Most prevalent neurodegenerative disorder of childhood
- Group of lysosomal storage diseases
- Unifying clinicopathologic features
  - clinical symptoms
  - progressive neuronal loss
  - autofluorescent storage material





MRI image source – A. Schulz; Poyato, et al. JIMD. 2011; 34(5):1083-93.

Clinical Trial Readiness in CLN3 Disease

Expand network of collaborating investigators

Standardize Data Elements

Validate Outcome Measures

Train Evaluators

Validate Biomarkers

Identify methods for testing new therapies

Understand Natural History

NINDS (U01NS101946)

Unified Batten Disease Rating Scale (UBDRS)

- Global Disease Assessment Tool
- Quantitative Ratings - 4 subscales
  - Physical Assessment (0-112) - 28 items
  - Seizure Assessment (0-54) - 12 items
  - Behavioral Assessment (0-55) - 9 items
  - Capability Assessment (0-14) - 5 items
- Sequence of Symptom Onset:

Conclusions

- Significant unmet therapeutic need in rare diseases
- Immense opportunity to expand application of platform therapies (gene-targeted therapies)
- Translational barriers prevent full realization of potential impact
  - Early and accurate diagnosis
  - Sufficient knowledge of natural history
  - Identification of responsive trial outcomes

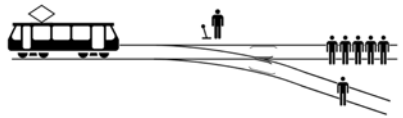
  - Site Principal Investigator and Co-Investigator for industry sponsored trials in rare genetic epilepsies
  - Principal investigator and Co-Investigator for n-of-1 anti-sense oligonucleotide (ASO) trials in neurodegenerative conditions and rare genetic epilepsies

How do you justify the risks? The cost? The effort?



What exactly are N-of-1 trials?

Too many sources of bias, how can we assess outcomes and risks?

Why are we bothering with N-of-1 trials and precision medicine?

But we do not even know if it works…

I think we should focus our efforts on the more common diseases, and help a larger number of people

This is just the “therapy du jour,” it is unlikely to be sustained

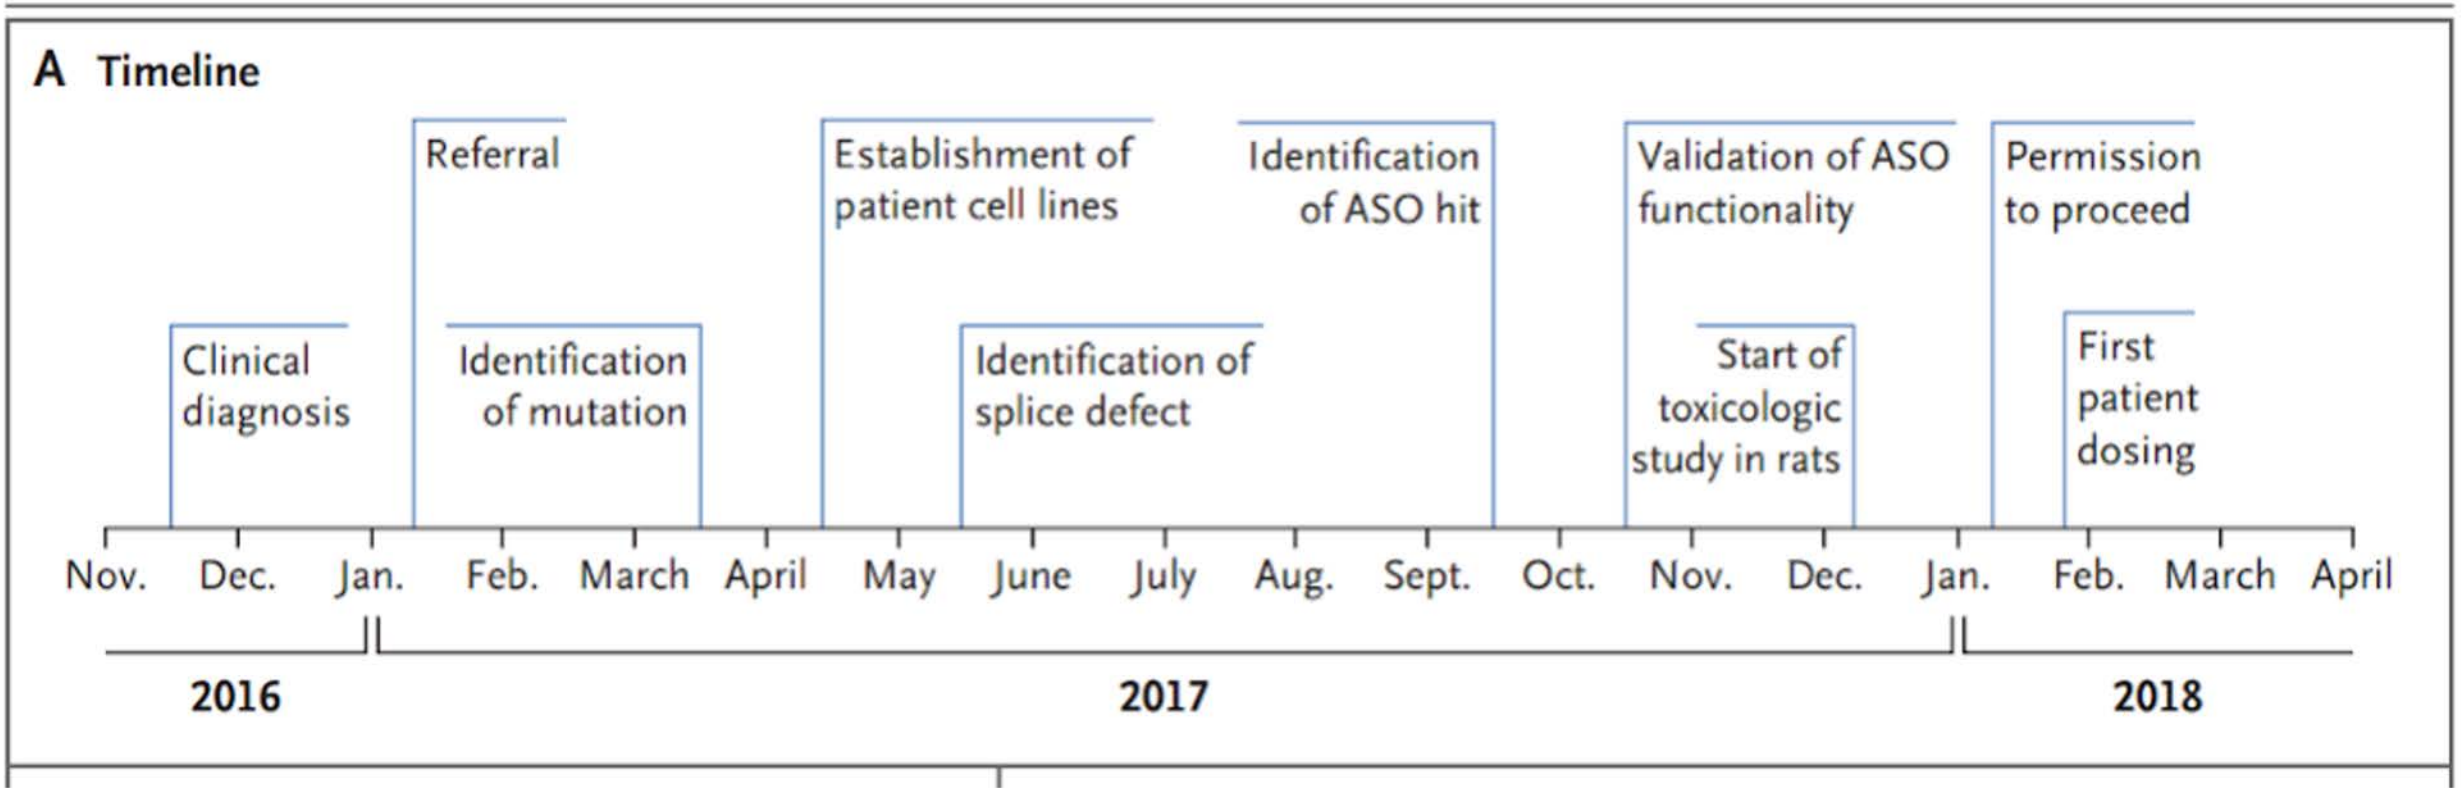
How soon can I start my patient on that therapy?

The story of a patient, a diagnostic odyssey, and the development of an N-of-1 therapy	
Definition of terms and concepts	
Historical perspective	
N-of-1 trials in Child Neurology	• Significance • Special considerations • Current landscape
The main variables	• Patient/disorder • Drug/target • Therapeutic goal/biomarkers
Pitfalls and special considerations	• Scientific capabilities, time, resources • Ethics
Possibilities and Promise of N-of-1 trials	

The story of a patient, a diagnostic odyssey, and the development of an N-of-1 therapy

- A healthy, bright 3 year old girl starts to have increased falls.
- She develops epilepsy.
- Over the span of 1-2 years, she starts to lose cognitive skills, speech, fine motor skills, ability to ambulate independently
- Serial MRIs show progressive atrophy involving the cerebellum
- There was still no diagnosis, despite extensive clinical genetic testing
- At age 6, research genome sequencing clenches the diagnosis, CLN7
- The race for a therapy begins…

Timeline of Milasen development

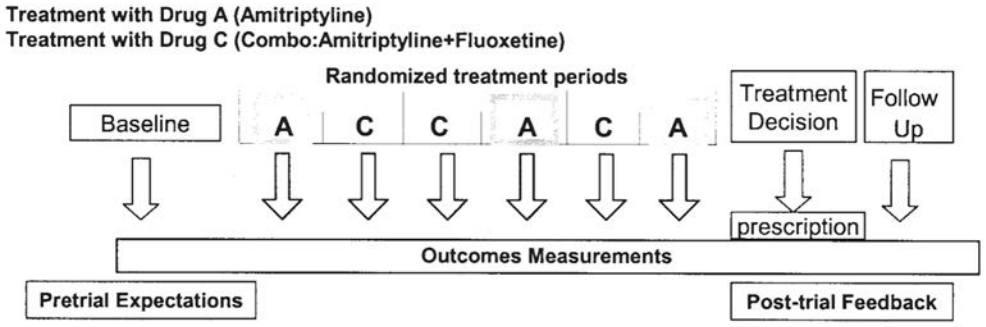


Kim J, Hu C., et. al, NEJM, 2019

What Exactly is an N-of-1 Trial? Some distinction is necessary

- According to Wikipedia, or the classic definition:

"An **N of 1 trial** is a clinical trial in which a single patient is the entire trial. A trial in which random allocation can be used to determine the order in which an experimental and a control intervention are given to a patient is an N of 1 randomized controlled trial."



Zucker et. al, JRheum, 2006

Design	Notes
A-B	Often the only possible method
A-A^1-A	Placebo design
A-B-A	Withdrawal design
A-B-A-B	Withdrawal design
A-B-A-B-A-B	Withdrawal design
A-B^1-B^2-B^3-B^n-A	effect of different versions of B

A= no treatment, A^1=placebo, B=treatment, B^n=treatment iterations

Conditions Necessary for N-of-1 Trials

Condition	Description
Nature of the disorder	Chronic, stable, slowly progressive, or frequently recurring/relapsing
Nature of the treatment(s)	Significant individual differences in treatment effects Uncertainty about best treatment Rapid onset of action Brief and safe washout periods
Outcome assessment	Validated, repeatable measures (e.g., biomarkers) of treatment effects
Stakeholders	Patients, health care providers, and health system willing to engage in N-of-1 trial effort

SOURCE: Adapted from Kravitz et al. 2014 [2]

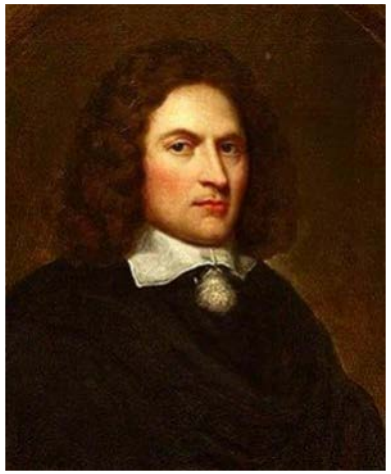
N-of-1 Trials in Our Current Context

- A single patient is the entire trial
- Therapy is **selected** or **designed** based on patient's particular disorder (e.g. genetic condition, +/- allele specific), and other physiological characteristics if applicable (e.g. pharmacogenomic profile)
- Patient is their own control (natural history of disorder is helpful, when available)
- While often patient specific, can be expanded to a small group (allele specific), or a relatively larger group (non-allele specific)
- An example of precision Medicine (used interchangeably with personalized medicine, no consensus on terminology)

"Precision medicine, sometimes known as "personalized medicine", is an innovative approach to tailoring disease prevention and treatment that takes into account differences in people's genes, environments, and lifestyles. *The goal of precision medicine is to target the right treatments to the right patients at the right time*"

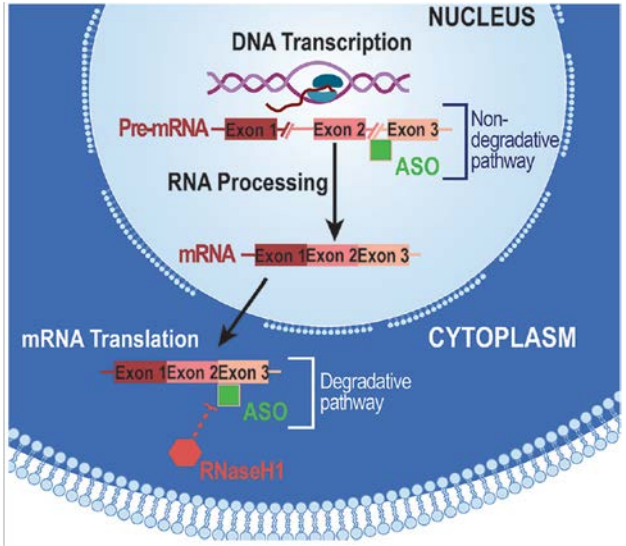
https://www.fda.gov/

Historical Perspective: From Laced Stockings to Allele-Specific ASO therapy



Richard Wiseman, surgeon to King Charles II, 1676

1950	Self recorded trials for “low-grade morbidity,” “efficacy of hypnotics”
1980 1990	• Concept brought to wider readership • Results of first trials published • User’s guide to N-of-1 trials
2000	• N-of-1 used in ADHD • Reporting guidelines, risk of bias
2010 2020	• Advances in genetic testing, possibility of precision therapies • Development of disease specific small molecule treatments • Pharmacogenomics • Gene Therapy • ASO (allele and non-allele specific) • Development of specific FDA regulatory pathways • NIH precision medicine initiative

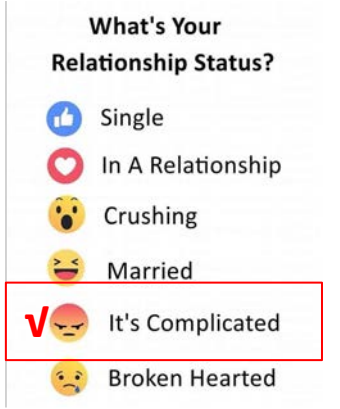


Van Laar A, Van Laar V et. al, Practcial Neurology, 2019

N-of-1 trials and Child Neurology: A Match Made in Necessity

- Put together, “rare” genetic disorders are very common in child neurology
- Several conditions do not respond to, or do not tolerate available therapies (e.g., epilepsy is refractory in about 30% of children)
- Neurodegenerative conditions (SMA, PME, NCL, CMT)
- Many disease mechanisms are unknown (or can only be targeted through genetic modification or chemical modification of mRNA)

N-of-1 trials and Child Neurology: A Match Made in Necessity, but…



- Many conditions are inherently static (e.g., brain malformations, developmental epileptic encephalopathies
- In neurodegenerative conditions, clinical symptoms and/or diagnosis lag behind irreparable neuronal loss (e.g. ALD)
- Drug delivery and target: blood, particular organ, spine, brain
- And then within the brain: differential distribution?
- Study design itself: use of placebos or cycles not ideal in neurodegenerative conditions
- Patient assent often impossible due to age, cognitive level, neurological regression

Very limited interventional window

N-of-1 Trials in Child Neurology: Current Landscape

- Examples from neurodevelopmental disorders, epilepsies, and neurodegenerative disorders
- Levels of precision in therapeutic target of N-of-1 therapies

N-of-1 Trials: Neurodevelopmental disorders

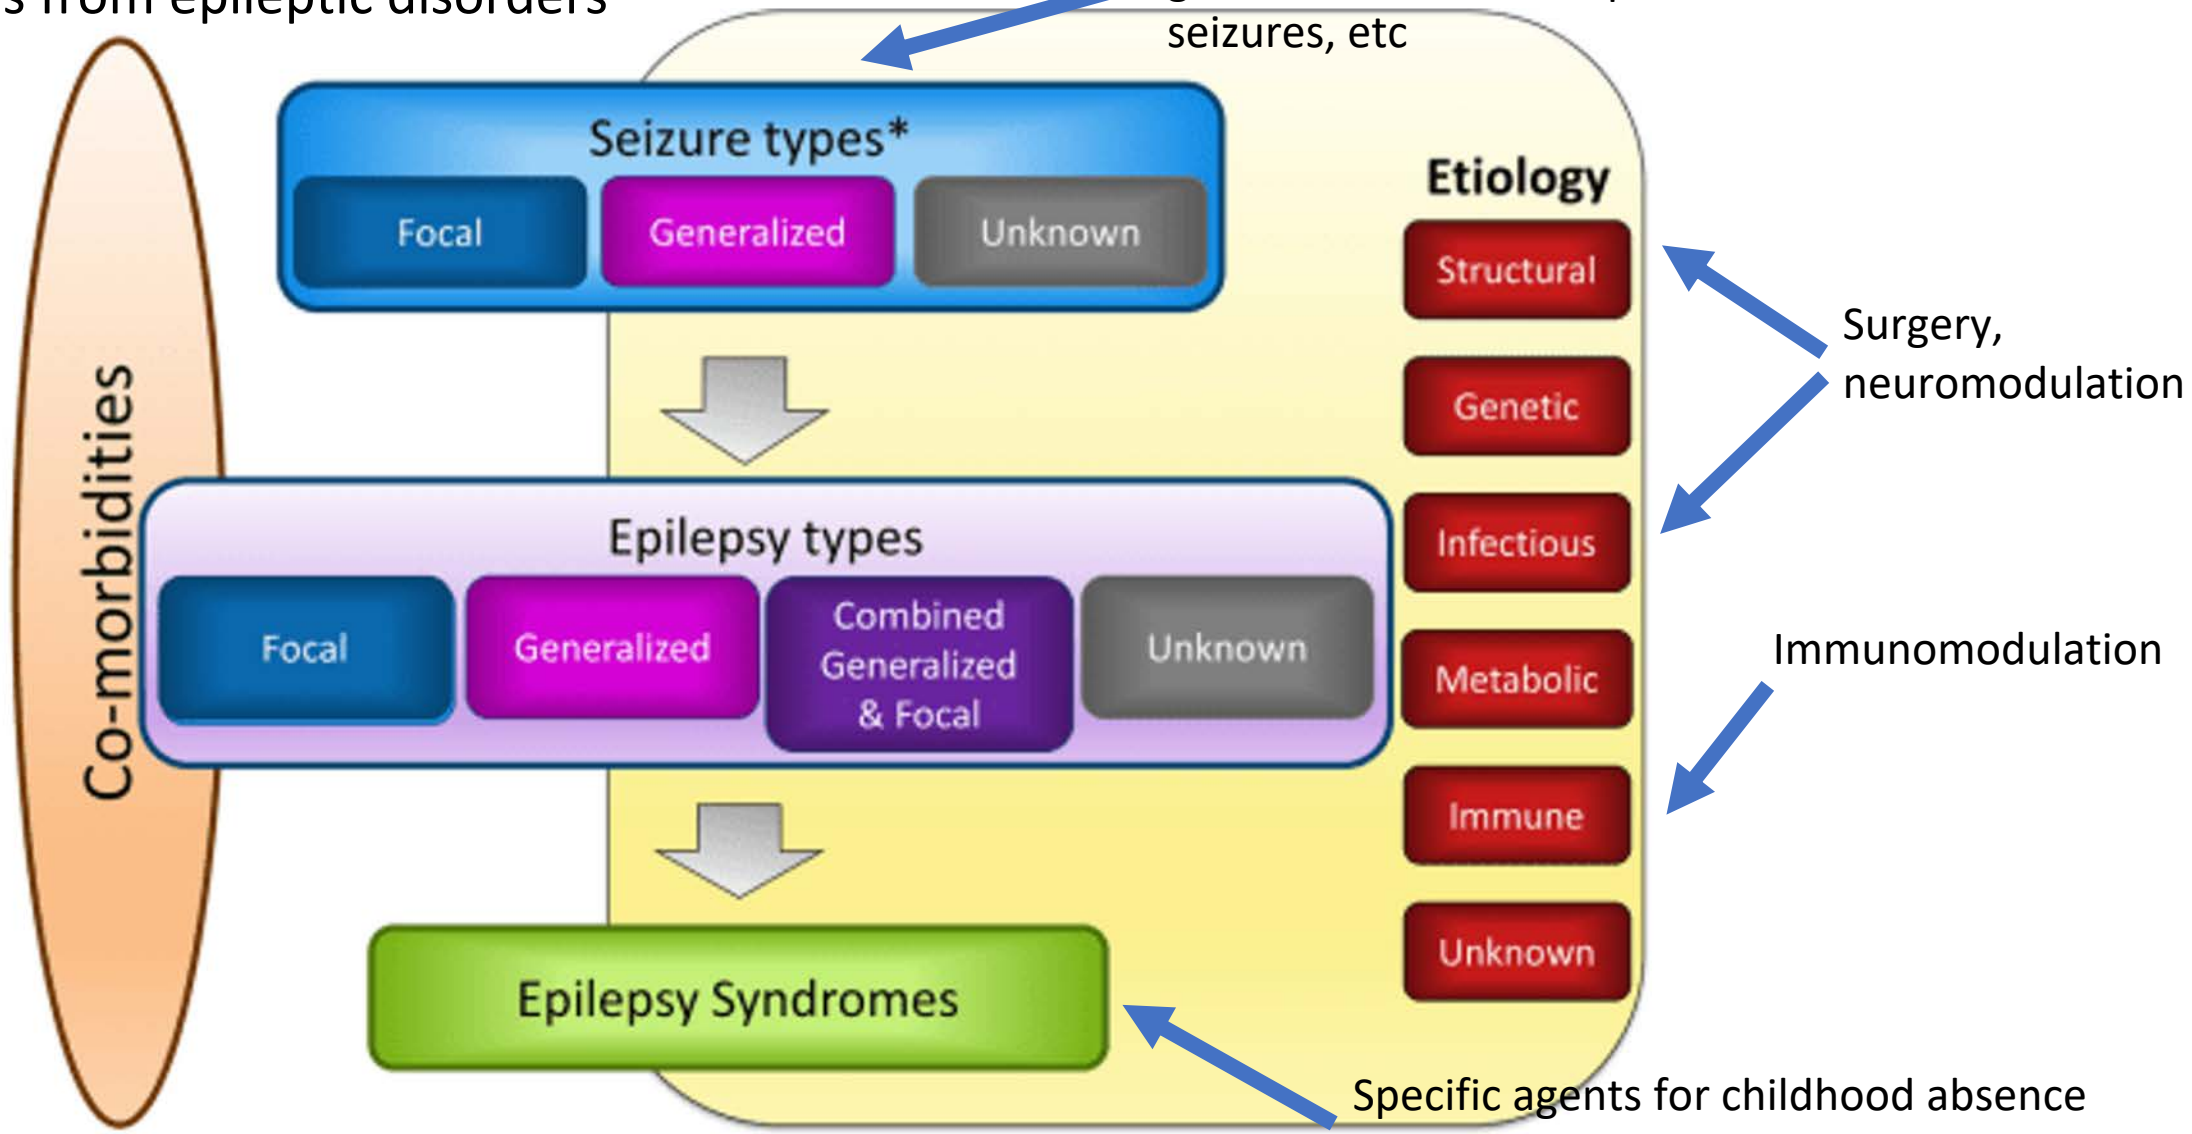
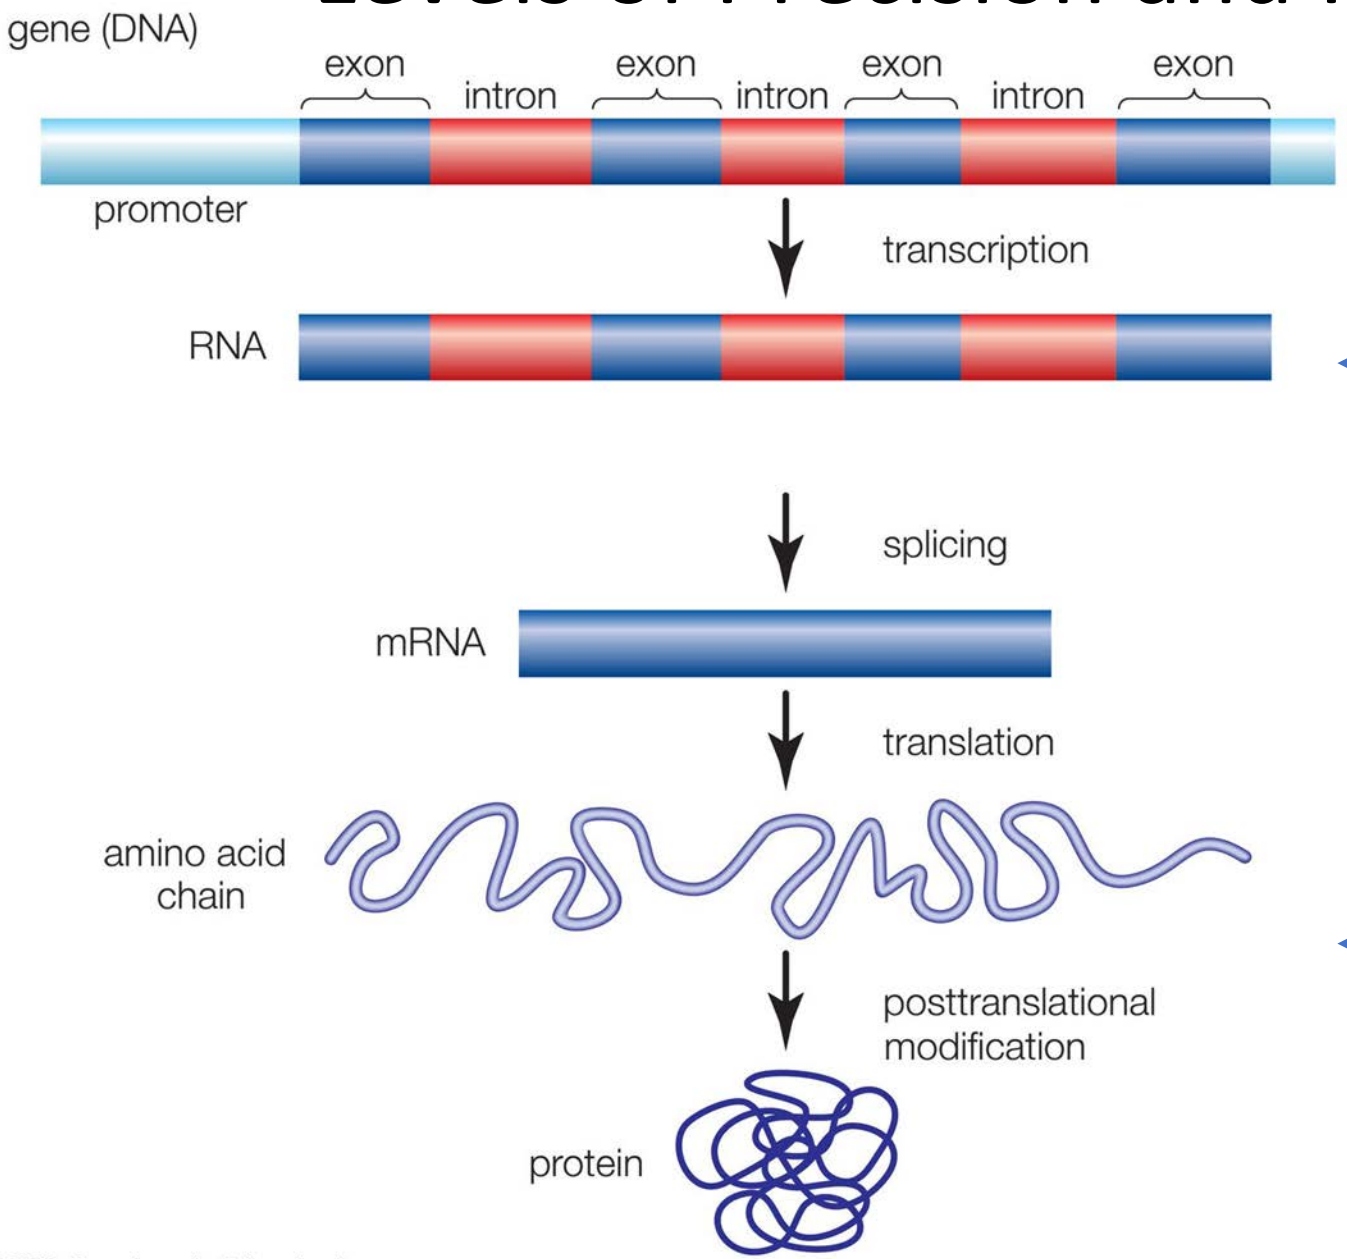
Different levels of precision medicine:
Examples from epileptic disorders



Levels of Precision and Intervention



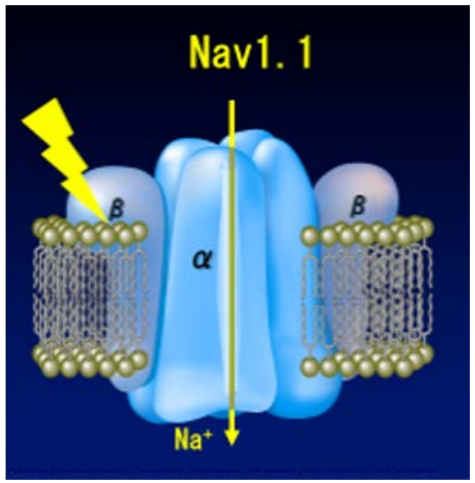
Targeted gene therapy.
CRISPR-Cas9

Anti-sense oligonucleotide (ASO) Therapy (allele specific v/s non-allele specific)

Targeting the effect of the abnormal protein including:

-Enzyme replacement
-Metabolite replacement
-Channel modulators, inhibitors, activators
-Pharmacogenomics

Common examples in epilepsy: Intervention at the protein function level

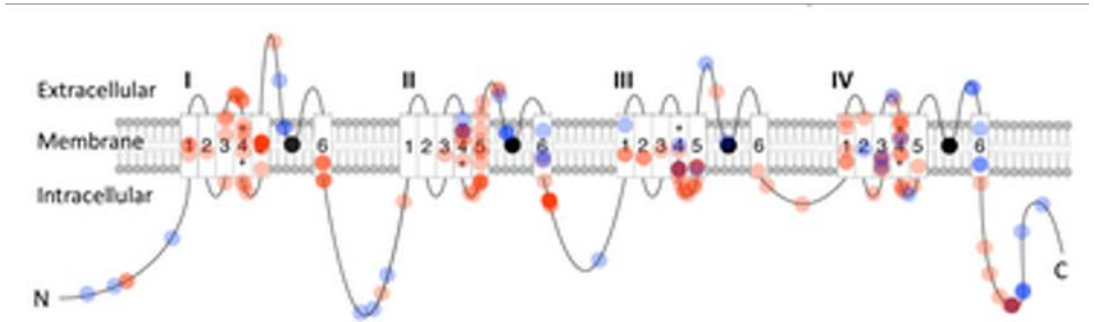


(SCN1A.NET)

Avoid further sodium channel blockade

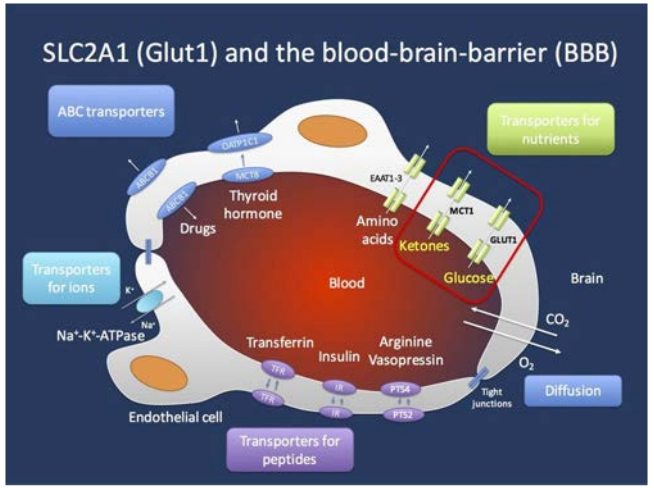
Several ASMs are recommended with various, non-specific mechanisms

ASO currently in phase I/II trial



(Simonsfoundation.org)

SCN2A: majority with gain of function
Sodium channel blockers recommended



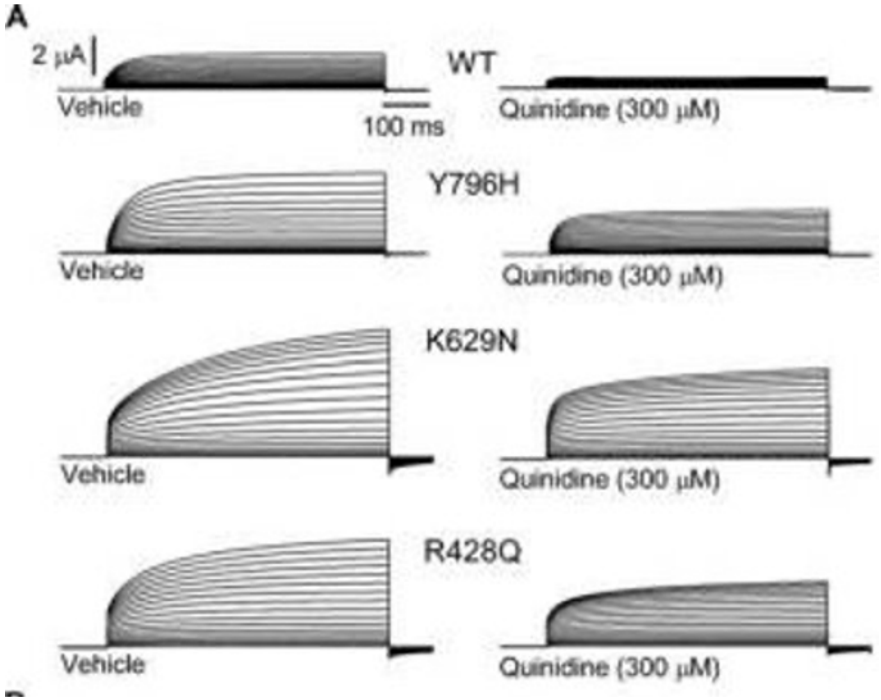
(epilepsygenetics.net)

Overcome the glucose transporter deficiency:

Ketogenic diet

Toward more precision:
Effect of specific variants on protein function

KCNT1 variant	In vitro response	Age at administration	Phenotype	Effect of quinidine on seizures
p.Y796H	Relatively mildblockade	11 years	Early onsetADNFLE	No significant response
K629N	Strong blockade	3 years	EIFMS	80% decrease
R428Q	Strongest blockade	3 years	EIFMS	>90% decrease



Mikati et. Al, Ann Neurol, 2016
Bearden et. Al, Ann Neurol, 2014

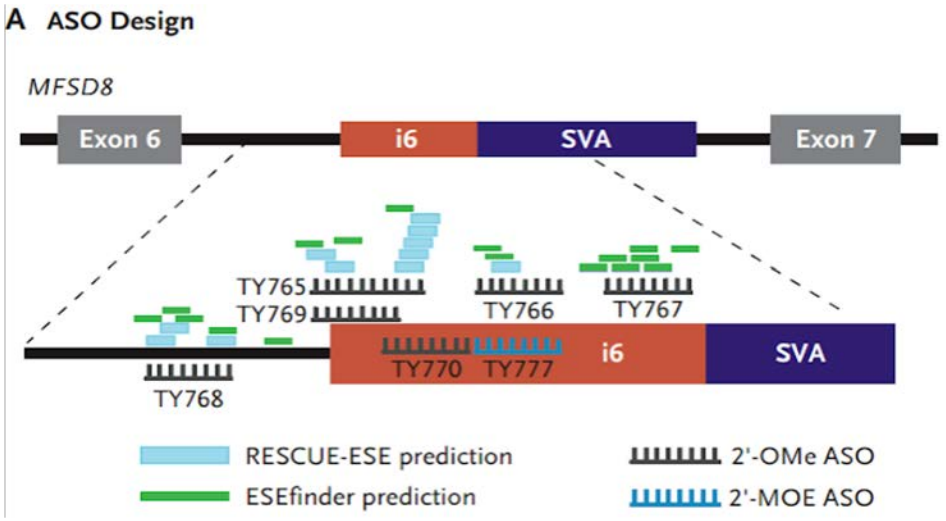
Toward even more precision: the Milasen example. Intervention at the mRNA level, with an allele specific ASO

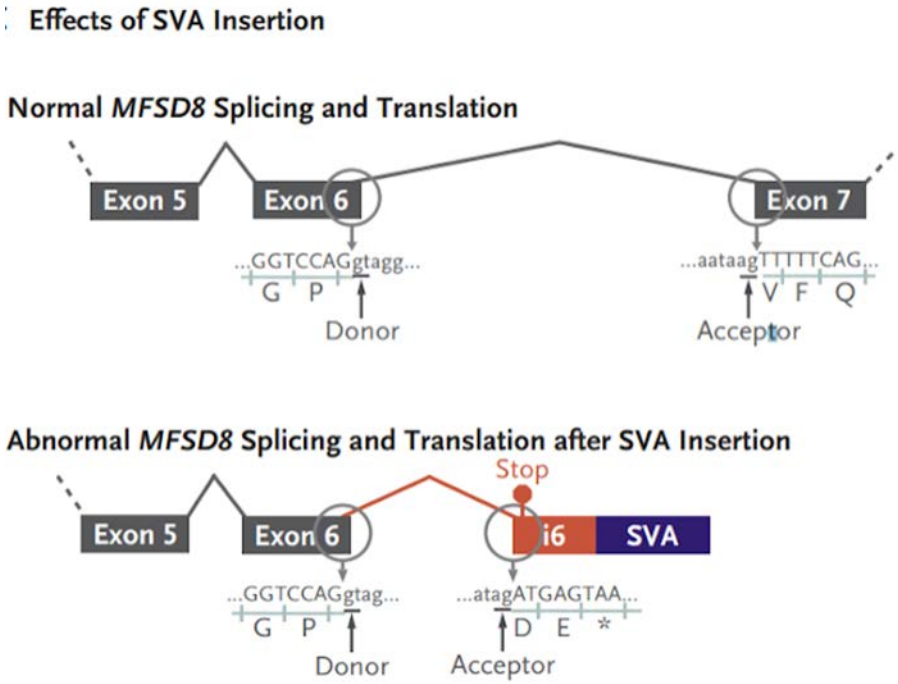
The NEW ENGLAND JOURNAL of MEDICINE

BRIEF REPORT

Patient-Customized Oligonucleotide Therapy for a Rare Genetic Disease

J. Kim, C. Hu, C. Moufawad El Achkar, L.E. Black, J. Douville, A. Larson, M.K. Pendergast, S.F. Goldkind, E.A. Lee, A. Kuniholm, A. Soucy, J. Vaze, N.R. Belur, K. Fredriksen, I. Stojkovska, A. Tsytsykova, M. Armant, R.L. DiDonato, J. Choi, L. Cornelissen, L.M. Pereira, E.F. Augustine, C.A. Genetti, K. Dies, B. Barton, L. Williams, B.D. Goodlett, B.L. Riley, A. Pasternak, E.R. Berry, K.A. Pflock, S. Chu, C. Reed, K. Tyndall, P.B. Agrawal, A.H. Beggs, P.E. Grant, D.K. Urion, R.O. Snyder, S.E. Waisbren, A. Poduri, P.J. Park, A. Patterson, A. Biffi, J.R. Mazzulli, O. Bodamer, C.B. Berde, and T.W. Yu





N-of-1 Trials and Patient Selection

- Established genetic diagnostic
- Known effect of genetic variant
- Failure, or non-existence, of other established therapeutic modalities
- Plausible mechanism for the therapy to lead to improvement/stabilization
- Availability of safety data
- Benefit outweighs risk
- Informed consent
- Clear, measurable outcomes and expectations

Other important factors: Patient selection in the context of resource allocation

- Severity of clinical state *(treat less v/s more severe?)*
- Stage of disease *(treat advanced v/s early/asymptomatic?)*
- Natural course of disorder *(prioritize neurodegenerative conditions v/s static epilepsies?)*
- Patient age *(treat younger v/s older?)*

Drug target: Anti-Sense Oligonucleotides (ASOs) as a model

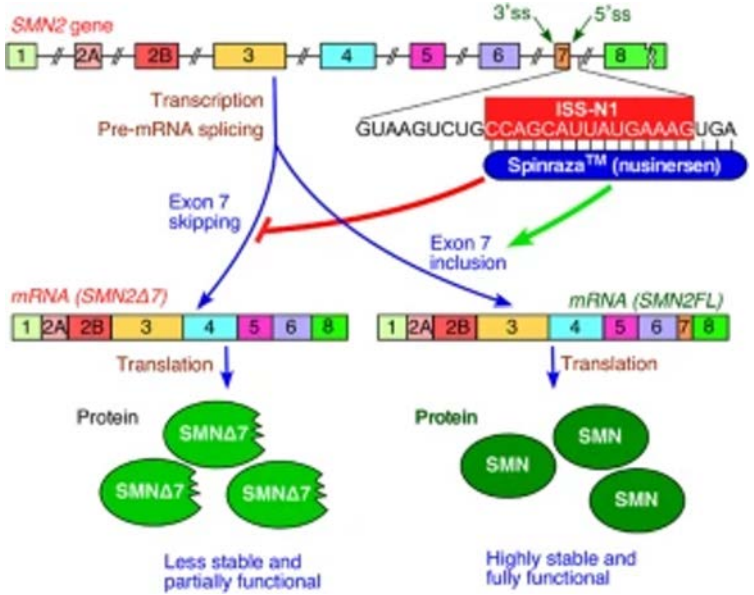
- Development and use for other neurological conditions was encouraged by the success of Nusinersen in children with SMA
- Why ASO's in N-of-1 therapies?
- Can be designed to target specific mRNA sequences and regions to affect how a particular gene is "read"
- Different techniques can lead to translation of a more functional protein, or change in the amount of a specific protein
- Can be allele specific, or non-allele specific (broadly affects overall function, e.g targeting the GoF or LoF pathogenicity)
- Therefore, it can be tailored to 1 patient or a small group of patients

Examples of ASO targets

- SMA: Splice modulating/exon inclusion of the otherwise skipped material (Allele specific- but very common allele)

  Dravet Syndrome: Alternative splicing/exon exclusion of the non-productive isoform (Non-allele specific, but must be a loss of function variant)

  CLN7, Milasen: splice correction affecting transposon unique to one of the patient's alleles, to produce a more functional MFSD8 protein



Singh NN et. al, Gene Therapy, 2017

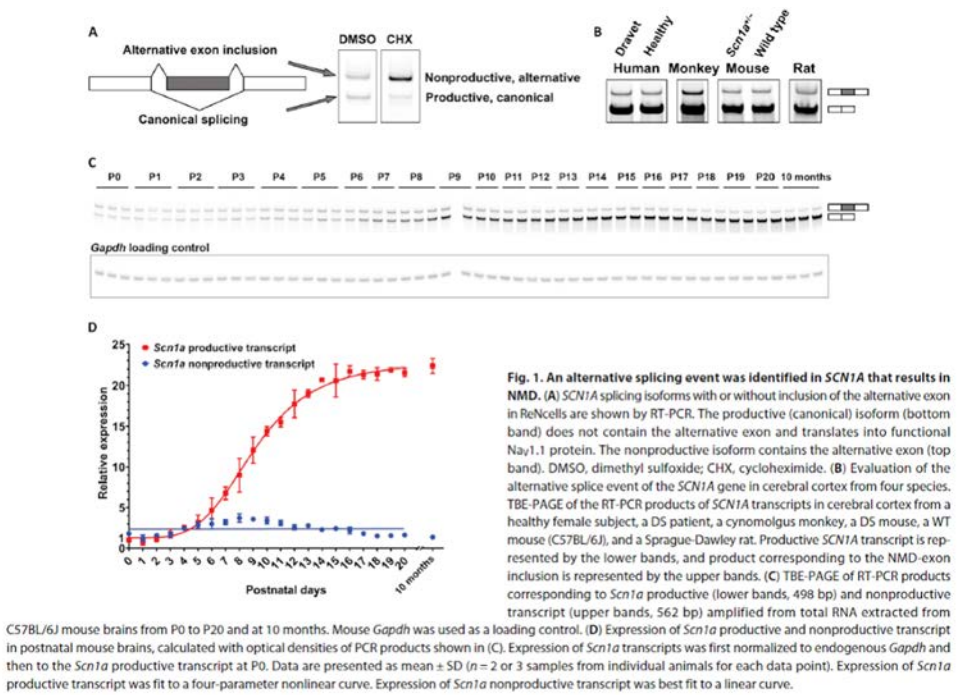


Fig. 1. An alternative splicing event was identified in *SCN1A* that results in NMD. (**A**) *SCN1A* splicing isoforms with or without inclusion of the alternative exon in ReNcells are shown by RT-PCR. The productive (canonical) isoform (bottom band) does not contain the alternative exon and translates into functional $Na_V1.1$ protein. The nonproductive isoform contains the alternative exon (top band). DMSO, dimethyl sulfoxide; CHX, cycloheximide. (**B**) Evaluation of the alternative splice event of the *SCN1A* gene in cerebral cortex from four species. TBE-PAGE of the RT-PCR products of *SCN1A* transcripts in cerebral cortex from a healthy female subject, a DS patient, a cynomolgus monkey, a DS mouse, a WT mouse (C57BL/6J), and a Sprague-Dawley rat. Productive *SCN1A* transcript is represented by the lower bands, and product corresponding to the NMD-exon inclusion is represented by the upper bands. (**C**) TBE-PAGE of RT-PCR products corresponding to *Scn1a* productive (lower bands, 498 bp) and nonproductive transcript (upper bands, 562 bp) amplified from total RNA extracted from C57BL/6J mouse brains from P0 to P20 and at 10 months. Mouse *Gapdh* was used as a loading control. (**D**) Expression of *Scn1a* productive and nonproductive transcript in postnatal mouse brains, calculated with optical densities of PCR products shown in (C). Expression of *Scn1a* transcripts was first normalized to endogenous *Gapdh* and then to the *Scn1a* productive transcript at P0. Data are presented as mean ± SD ($n = 2$ or 3 samples from individual animals for each data point). Expression of *Scn1a* productive transcript was fit to a four-parameter nonlinear curve. Expression of *Scn1a* nonproductive transcript was best fit to a linear curve.

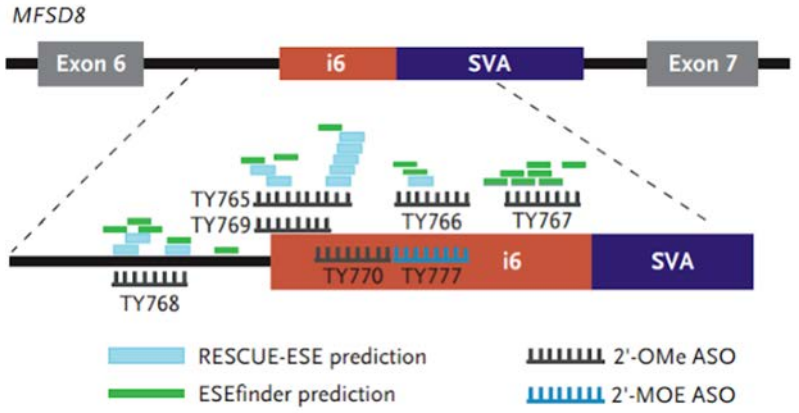
Han et. al, Science Translational Medicine, 2020



Kim J, Hu C., et. al, NEJM, 2019

ASO development for neurodegenerative conditions

Table ASO therapeutics for neurodegenerative disease

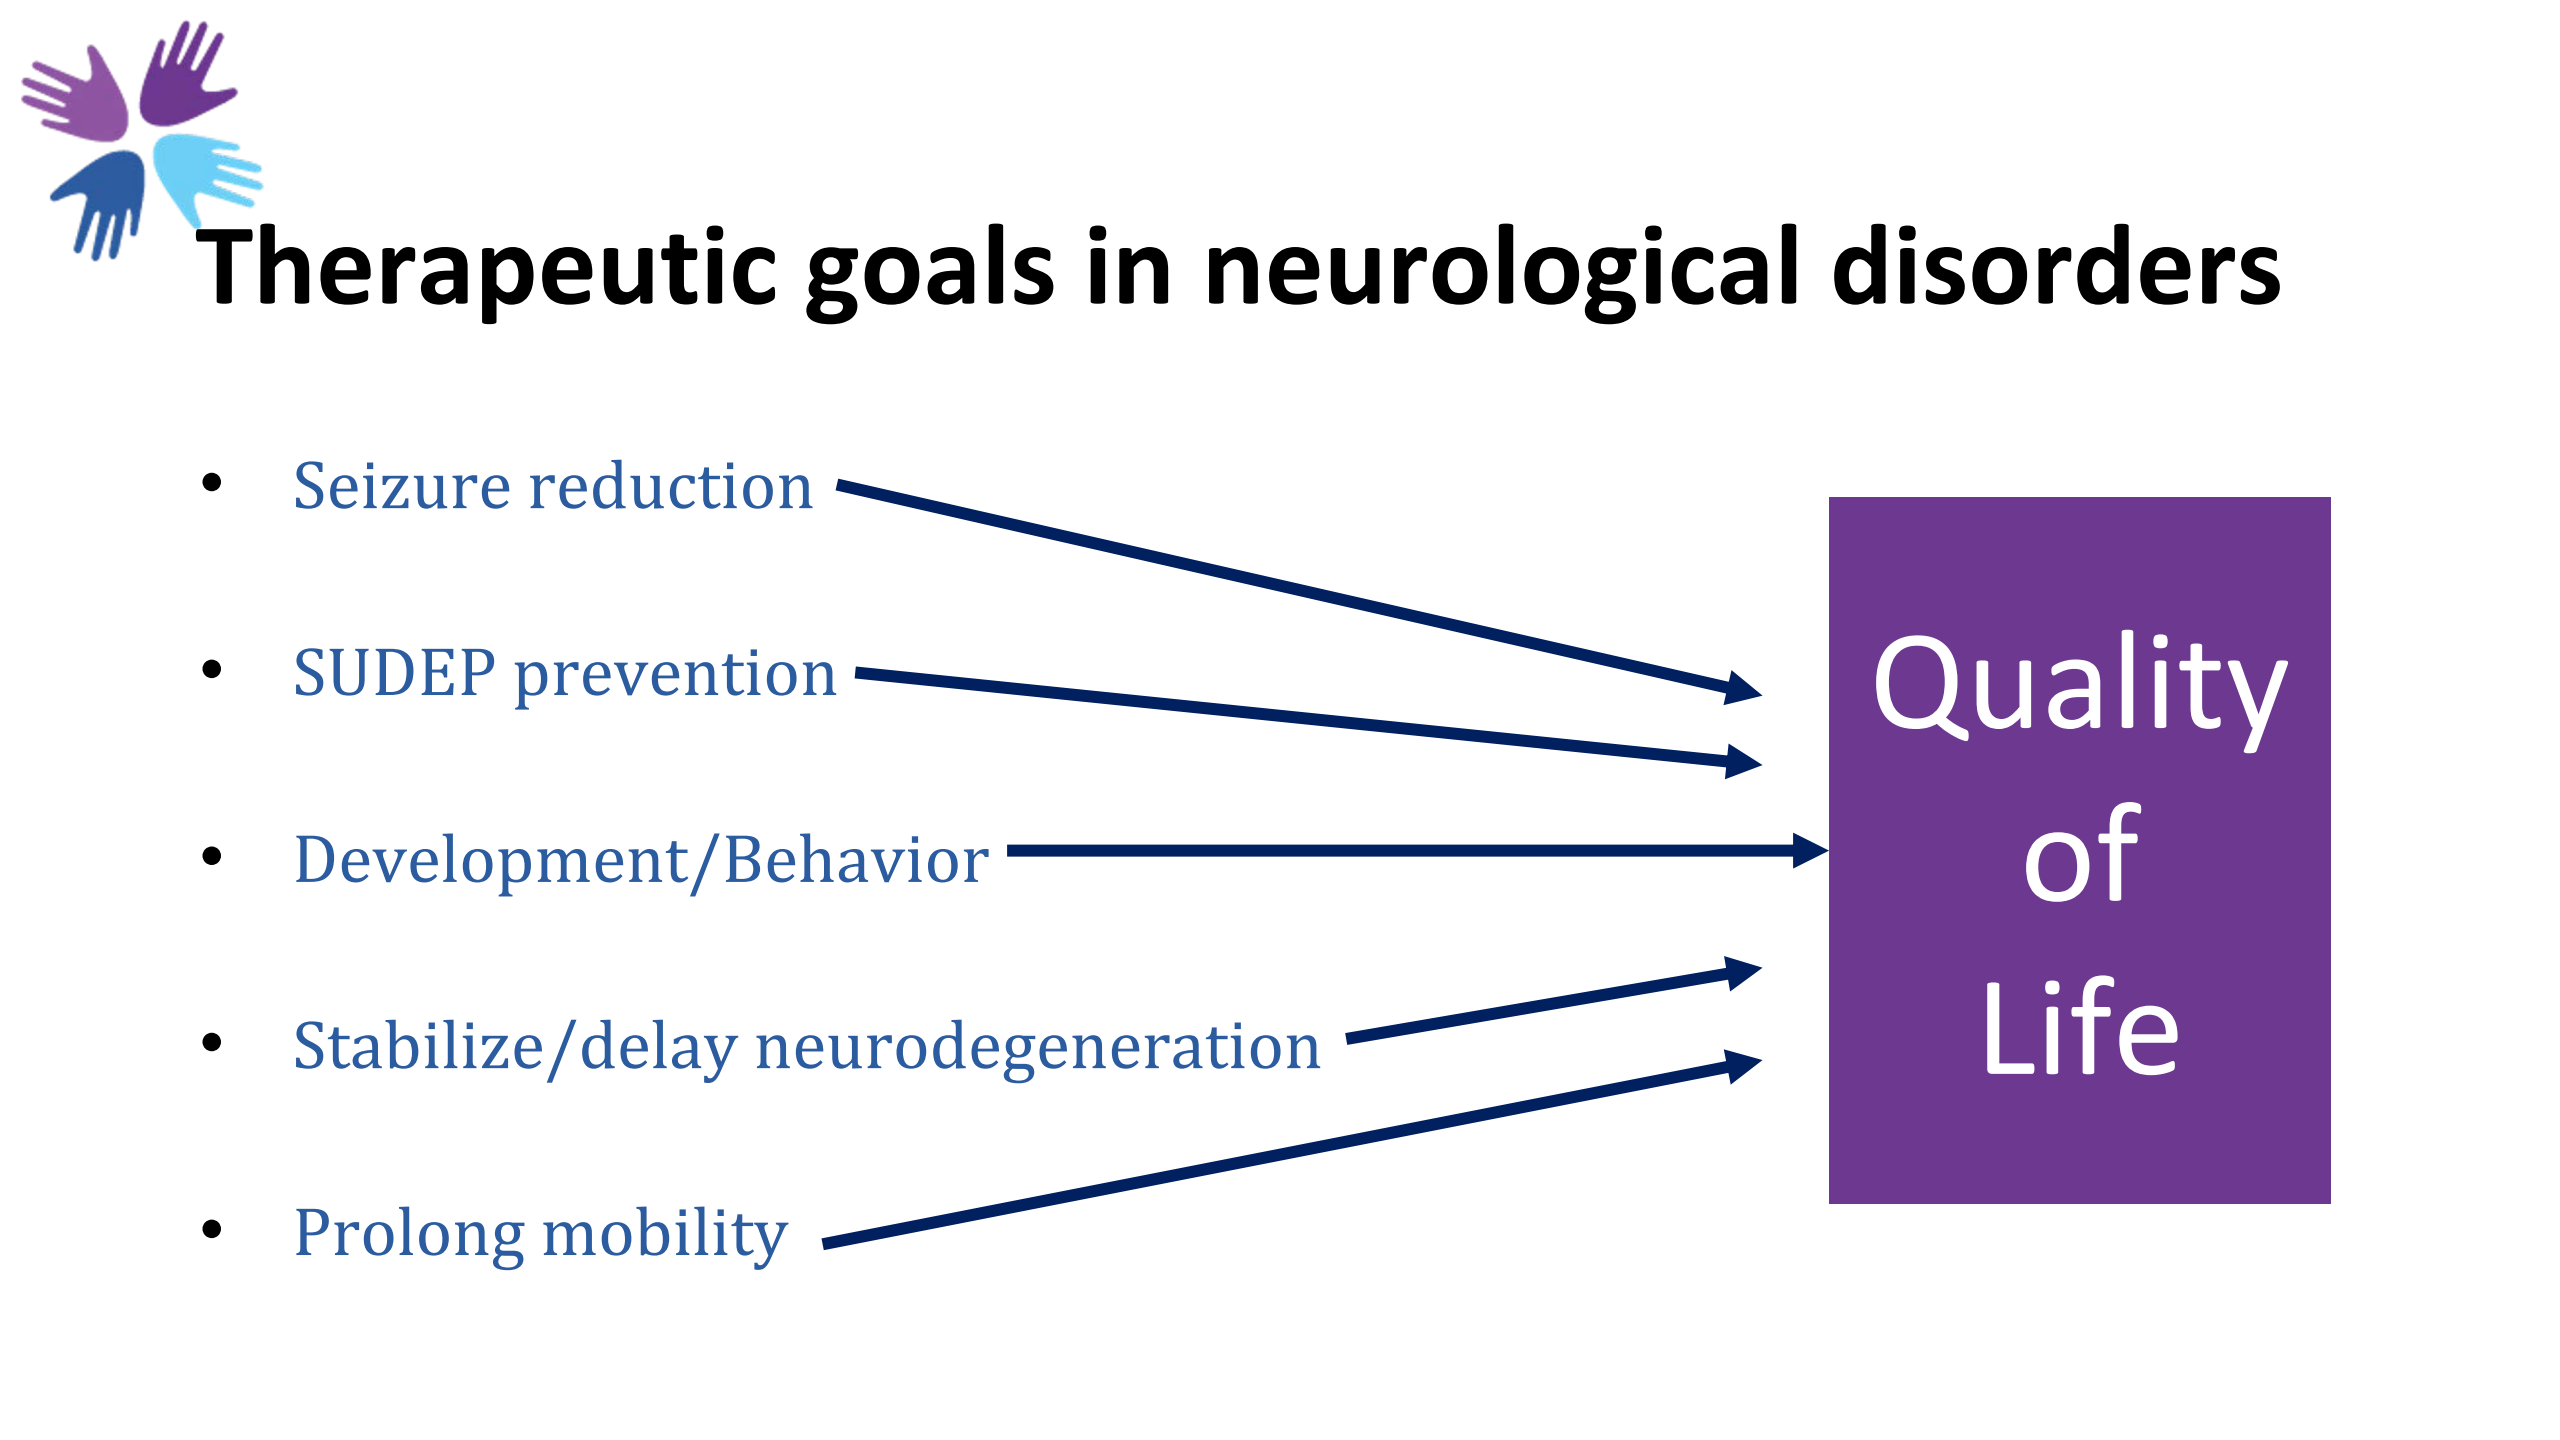
Drug	Indication	Target	ASO chemistry	Status
Nusinersen	SMA	*SMN2*, exon-7 inclusion	ASO, full 2′-MOE	FDA approved
Eteplirsen	DMD	*DMD*, exon-51 skipping	Morpholino	FDA approved
Inotersen	FAP	*TTR* expression	ASO MOE gapmer	FDA approved
WVE-210201	DMD	*DMD*, exon-51 skipping	Stereopure ASO	Phase 1 clinical trial
RG6042	HD	*HTT* expression	ASO MOE gapmer	Phase 3 clinical trial
WVE-120101	HD	*HTT* expression	Stereopure ASO	Phase 1/2 clinical trial
WVE-120102	HD	*HTT* expression	Stereopure ASO	Phase 1/2 clinical trial
IONIS-MAPTRx	AD	*Tau* expression	ASO MOE gapmer	Phase 1/2 clinical trial
BIIB078	ALS	*C9ORF72* expression	ASO MOE	Phase 1 clinical trial
IONIS-SOD1Rx	ALS	*SOD1* expression	ASO MOE gapmer	Phase 1 clinical trial
ATXN2 ASO	SCA2	*ATXN2* expression	ASO MOE gapmer	Preclinical development[38]
ATXN3 ASO	SCA3	*ATXN3* expression	ASO MOE gapmer	Preclinical development[42]

Abbreviations: AD = Alzheimer disease; ALS = amyotrophic lateral sclerosis; ASO = antisense oligonucleotide; DMD = Duchenne muscular dystrophy; FAP = familial amyloid polyneuropathy; FDA = Food and Drug Administration; HD = Huntington disease; MOE = methoxyethyl; SCA = spinocerebellar ataxia; SMA = spinal muscular atrophy.

Scoles DR. et. al, Neurol Genet, 2019

Therapeutic goals in neurological disorders

- Seizure reduction
- SUDEP prevention
- Development/Behavior
- Stabilize/delay neurodegeneration
- Prolong mobility



Selecting and defining an outcome measure

Clinical measures

- e.g: seizure frequency, developmental trajectory, mobility assessment

Biomarkers

- Neuroimaging (rate of atrophy, volumetric analysis, signal analysis)
- Neurophysiology (EMG/NCS, EEGs with analysis of frequency/continuity)
- Molecular (Byproducts, levels of normal or abnormal proteins in serum and CSF)

Pitfalls and special considerations: Scientific limitations

- Animal models, with fair replication of human phenotype, are not easily available
- Biomarkers for target engagement and standardized outcome measures not always available

The problem with outcomes and biomarkers

Clinical measures

e.g: seizure frequency, developmental trajectory, mobility assessment

Subjective, variable, lack of detailed natural history studies, patient-to-patient variability

Biomarkers:

- Neuroimaging (rate of atrophy, volumetric analysis, signal analysis)

  Variable, lack of controls
- Neurophysiology (EMG/NCS, EEGs with analysis of frequency/continuity)

  Largely unknown significance
- Molecular (Byproducts, levels of normal or abnormal proteins in serum and CSF)

  Unknown significance as surrogate for clinical function, and most of the time unavailable

Therapy related challenges

- Novel therapy: proof of concept, Pre-clinical (safety data, animal models and their limitations), manufacturing, resources, cost
- Existing therapy: drug availability, acquisition, cost
- Drug administration: oral, intravenous, intrathecal, intraventricular
- Drug properties: pharmacokinetics, pharmacodynamics, blood brain barrier permeability
- Side effects and risks, which are largely unknown

Ethical considerations: Resource allocation

- Finite resources
- How does the cost of treatment get covered?
- Should therapies impacting the maximum number of people be prioritized over those impacting fewer people?
- But where would that leave patients with rare/orphan diseases?

Inherent bias in precision medicine: Genomic disparity

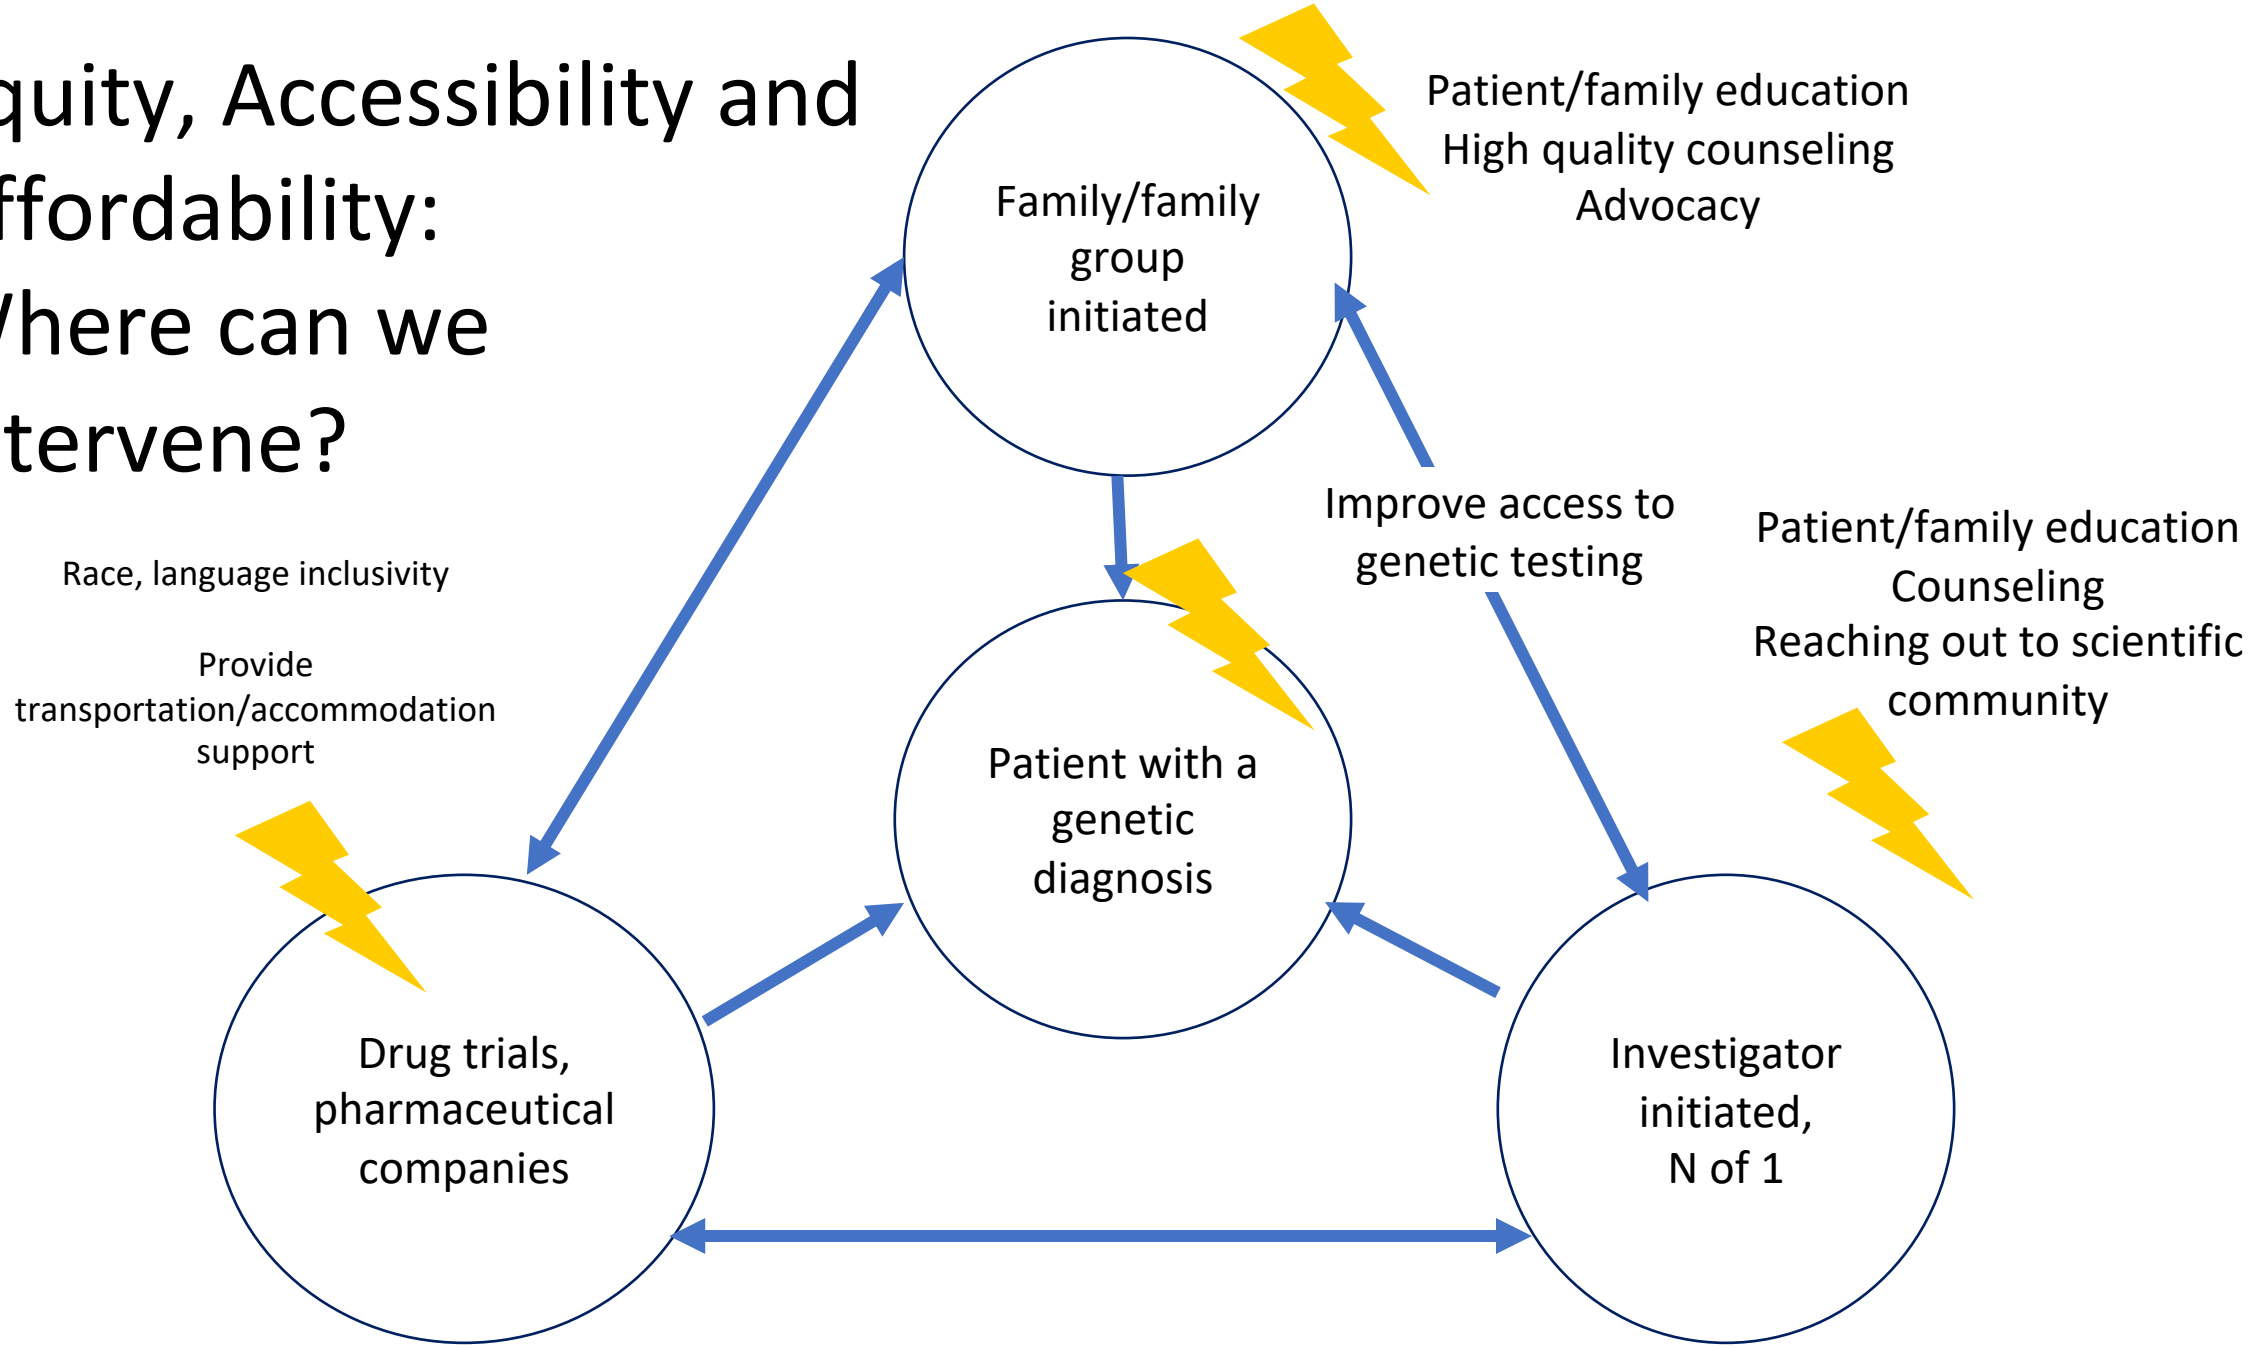
- Reliance on high quality data/genetic information
- Most population samples (e.g. genome-wide association studies) 80% of participants are of European ancestry, 3-5% African and Hispanic
- Disparities extend to other under-represented groups including LGBTQ communities, undocumented, uninsured individuals, etc.

Lee S., The American Journal of Bioethics, 2020

Ethical consideration: The patient

- Patient selection
- Patient wishes/assent
- Measuring quality of life through caregivers

Equity, Accessibility and Affordability: Where can we intervene?



Future possibilities through N-of-1 trials and precision medicine

- High need for such therapies in rare neurogenetic conditions
- Drug selection and development should be highly evidence based
- N-of-1 trials can lead to larger scale trials and advance understanding of pathogenic mechanisms and drug development
- Need for strict regulatory mechanisms, independent ethical and scientific oversight

Drug Regulation in the Era of Individualized Therapies

Janet Woodcock, M.D., and Peter Marks, M.D., Ph.D.

N Engl J Med, 2019

If such individualized interventions become common, and some are successful, the questions of regulatory approval and sustainability of production also become pertinent. Some investigational products, such as snake antivenins, have remained investigational for decades, maintained by various nonprofit or governmental organizations. Approvals as variations on a well-characterized archetypal product might be feasible if the interventions are closely related. Finally, finding sustainable funding for such interventions may prove challenging, because the cost of production can be quite substantial, particularly for gene therapies. In the upcoming months, these issues will need to be addressed at the FDA with input from academic, patient advocate, pharmaceutical industry, and other stakeholders.

BOSTON • MASSACHUSETTS

Genetic Diagnosis – why does it matter?

- Improve prognosis counseling
- Enable discussion of recurrence risk
- May affect choice of medications
- Provide research opportunities
- Connect families with the same diagnosis
- Goal: Implement targeted therapy

50TH ANNUAL MEETING
CNS
SEPT 29-OCT 2, 2021

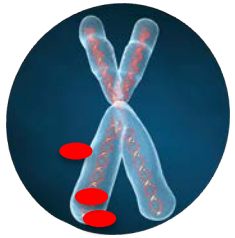
Genetic testing options in pediatric neurology

Chromosome array

Deletions, duplications, unbalanced translocations



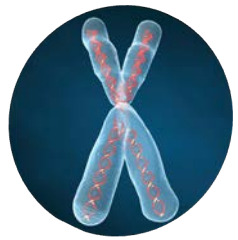
Gene Sequencing

Gene Panel

Dozens to hundreds of genes known to cause a disorder or group of disorders

Exome

All ~20,000 genes in human genome (~4,600 known to cause disease)



Whole Genome Sequencing

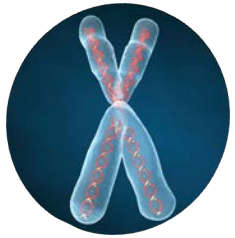
100% of DNA

RNA Sequencing

Genetic testing: Diagnostic yield matters

Chromosome array

5-30%



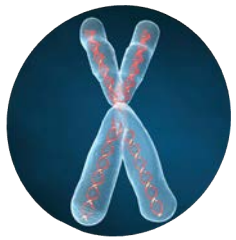
Gene Sequencing

Gene Panel

Up to ~20-30%

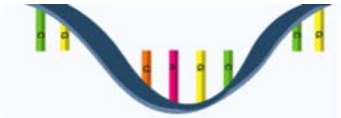
Exome

~25-50%

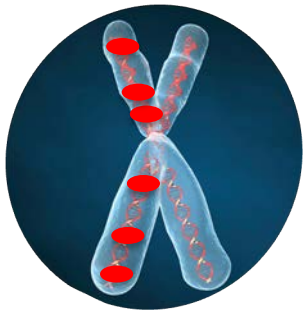


Whole Genome Sequencing

???



Genetic testing: Early-onset epilepsy



Exome
~25-50%

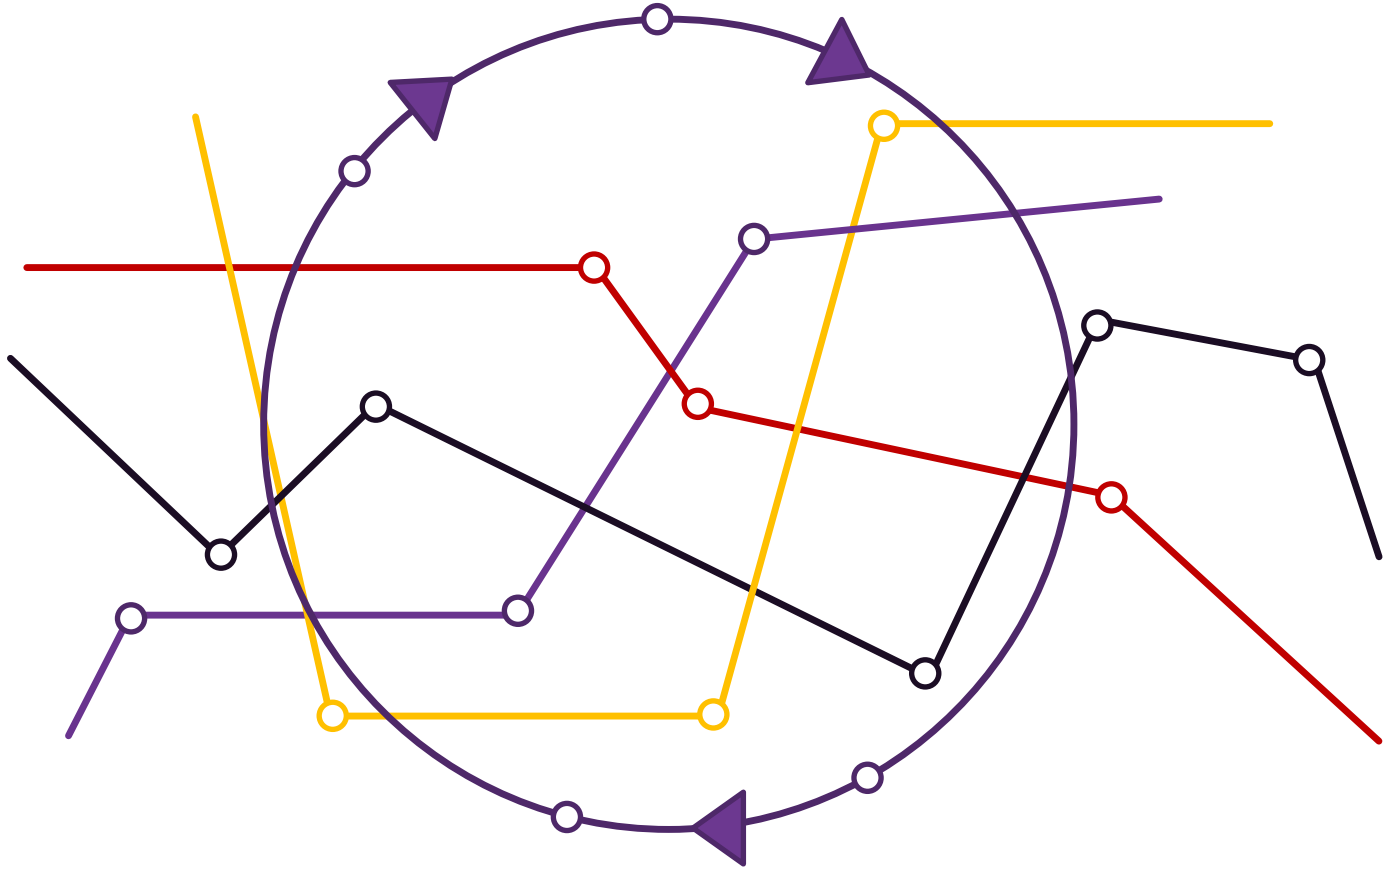
>

Gene Panel
Up to ~20-30%

>

Array
5-10%

Diagnostic odysseys take many forms

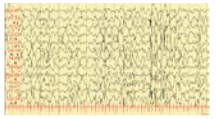


Diagnostic Odyssey #1

6 mo
? delays

9 mo
array
47,XXY

8 mo



+ lots of normal tests

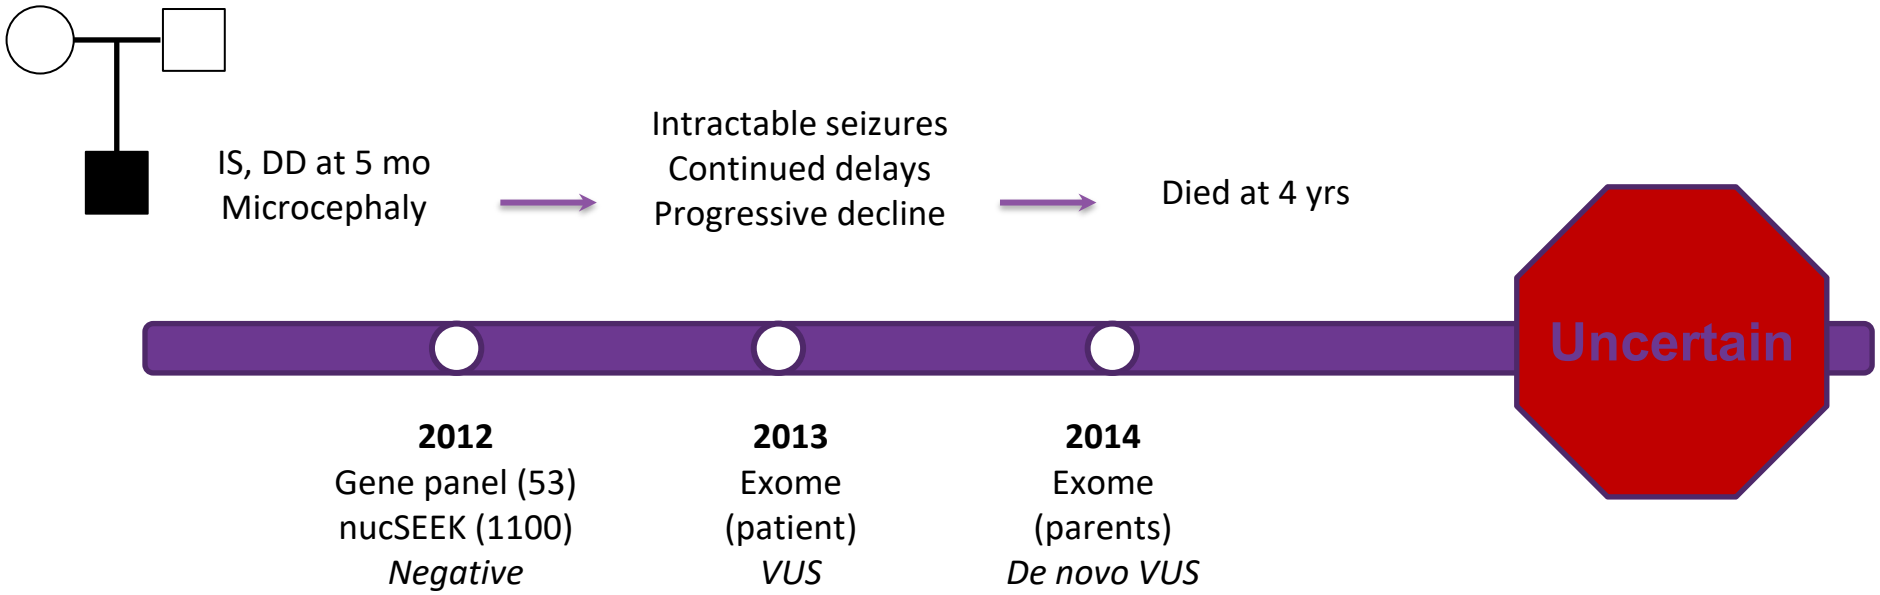
15 mo - 327
gene panel sent
Result: VUS (x4)

20 mo – parental testing
VUS x4 inherited

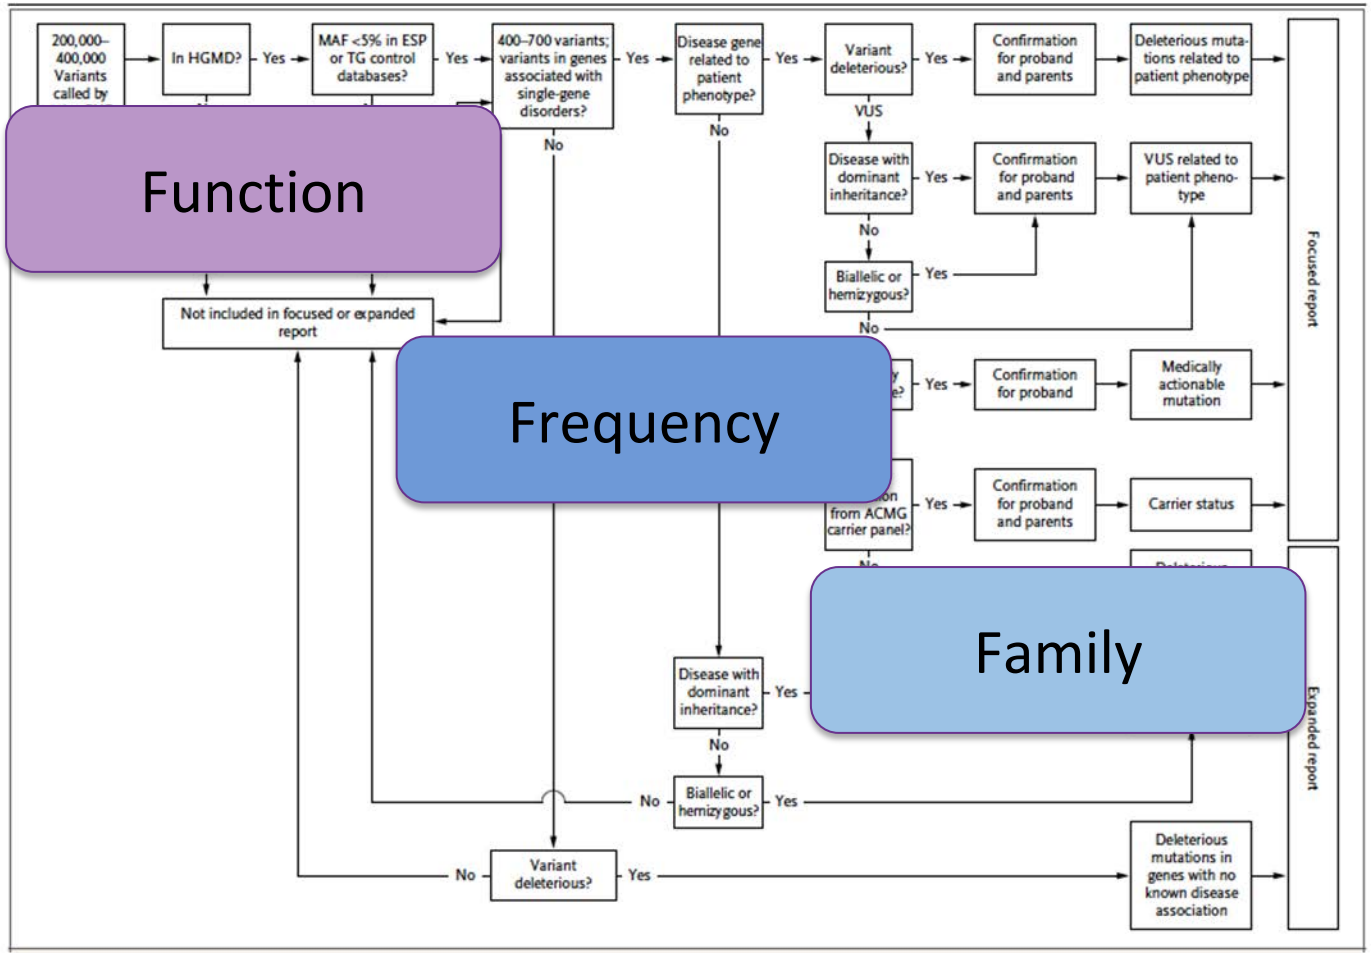
Metabolic genetics
Additional testing
(Nondiagnostic)

No Diagnosis

Diagnostic Odyssey #2



What goes into variant interpretation?



Function

Impacts protein

- Missense, splice, frameshift

Predicted to be deleterious

- Polyphen, SIFT, MutationTaster, CADD….

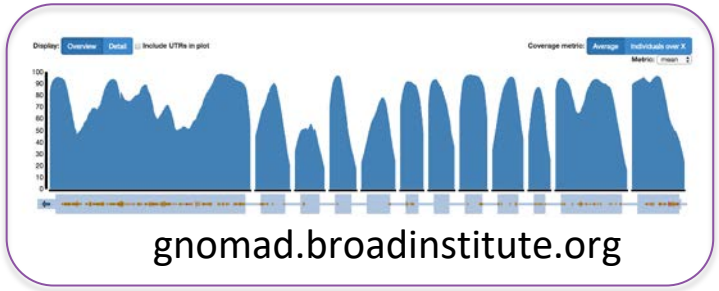
Consistent with disease mechanism

- Loss vs gain of function, location of mutation

Frequency

Severe, rare, sporadic disease

- *De novo* dominant: Disease-causing variants should be absent or ultra-rare in unaffected individuals



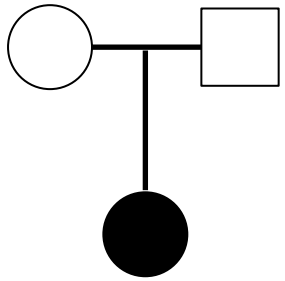
gnomad.broadinstitute.org

Rare, recessive disease

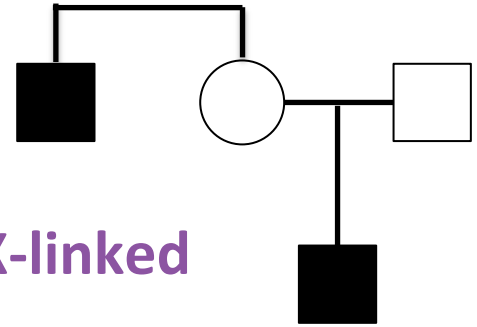
- Carriers may be present in the population
- Frequency will still be “rare”

ClinGen
Clinical Genome Resource

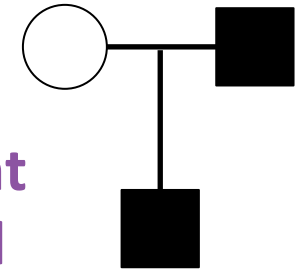
Family



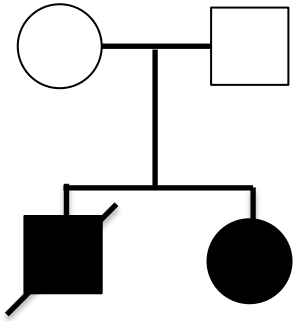
De novo



X-linked



Dominant inherited



Autosomal recessive

Genetic testing – interpretation

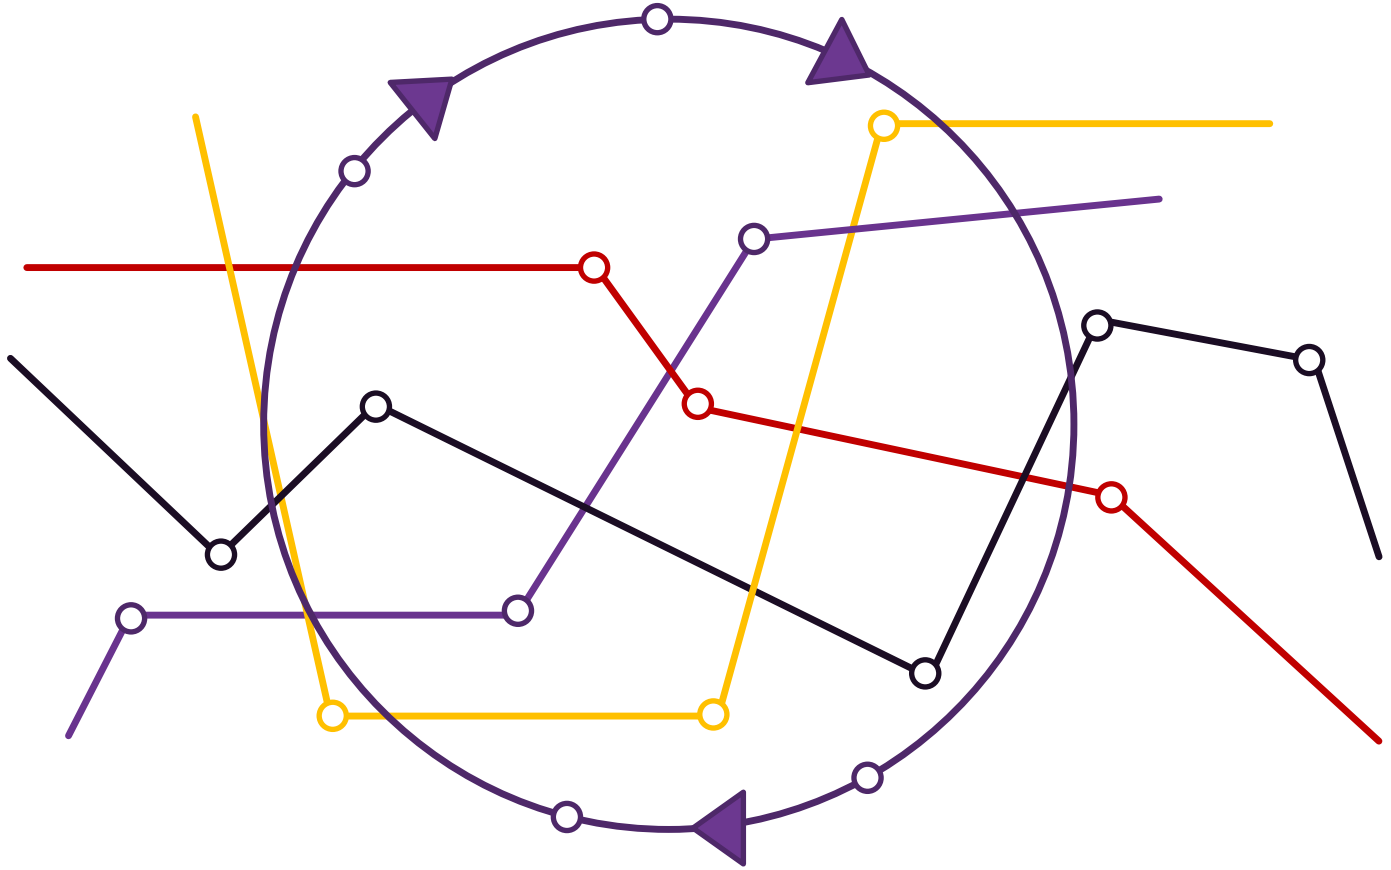
VARIANT INTERPRETATION

- Benign / likely benign
- Variant of Uncertain Clinical Significance (VUS)
- Likely Pathogenic
- Pathogenic

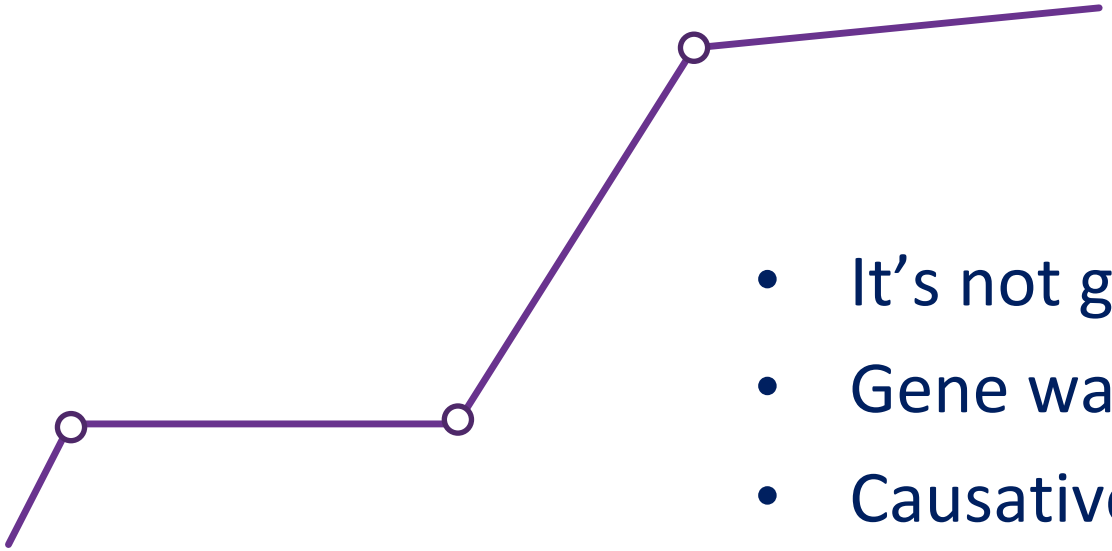
TEST INTERPRETATION

- Non-diagnostic / negative
- Diagnostic / positive

Diagnostic odysseys take many forms

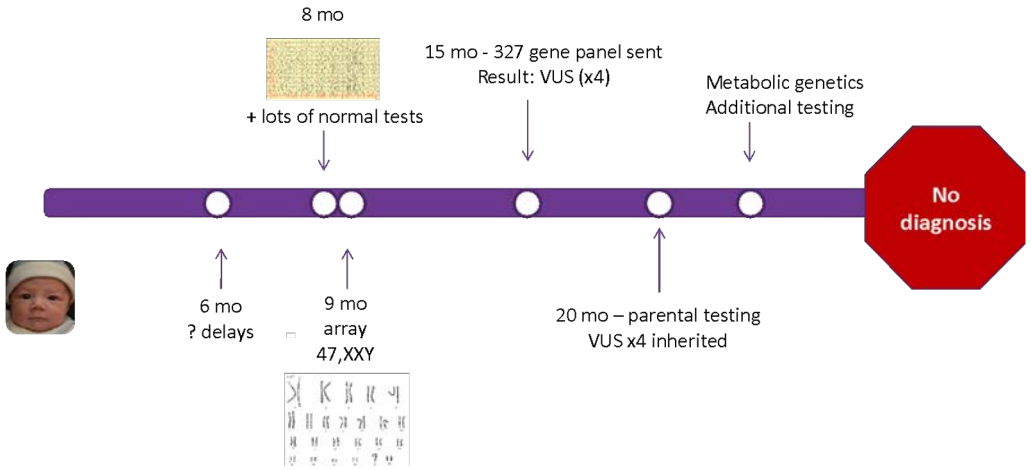


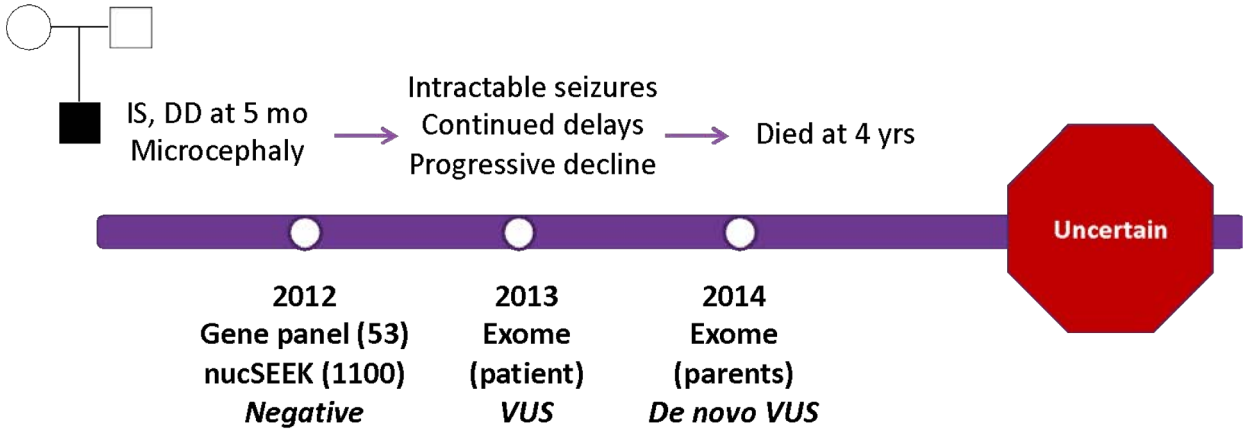
~~Diagnostic~~ odysseys take many forms



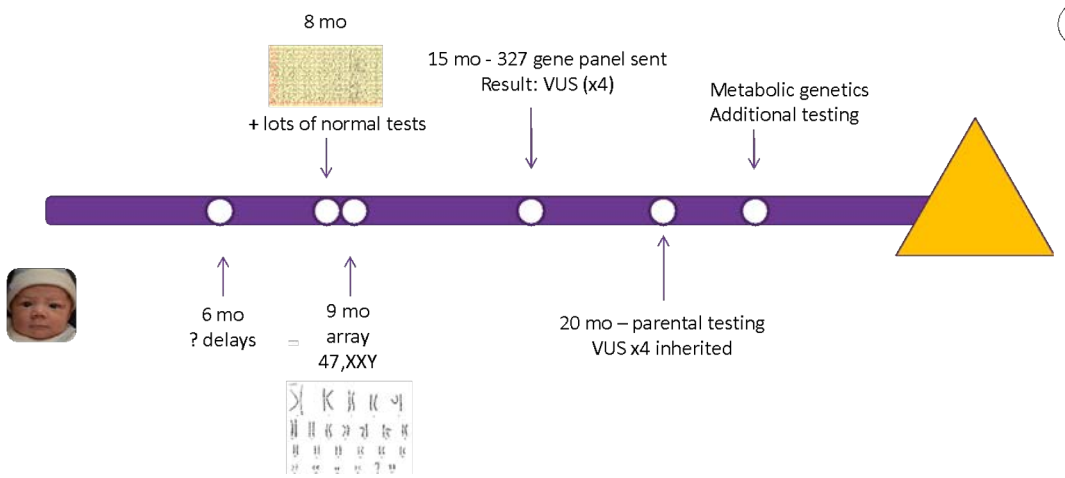
- It’s not genetic
- Gene wasn’t on the panel
- Causative gene not discovered yet
- Variant missed for technical reasons
- Variant misinterpreted

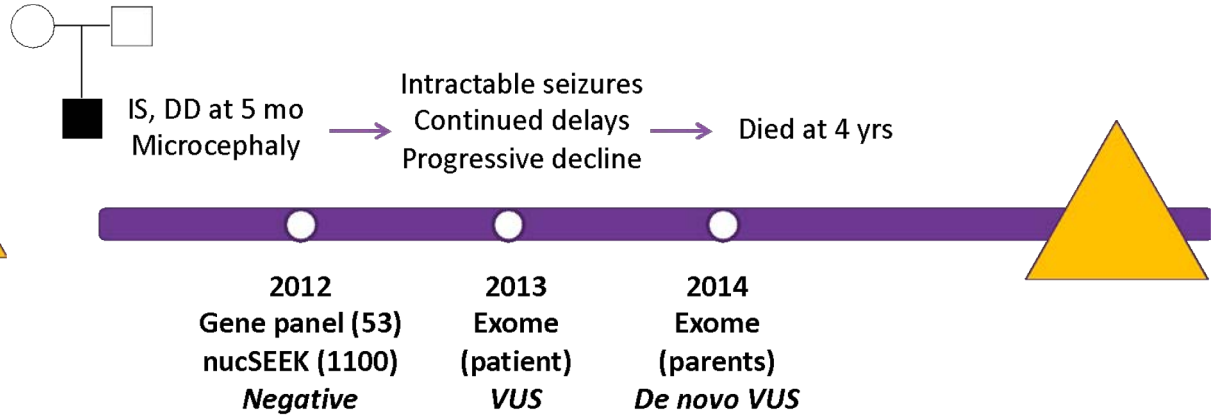
End of the line?



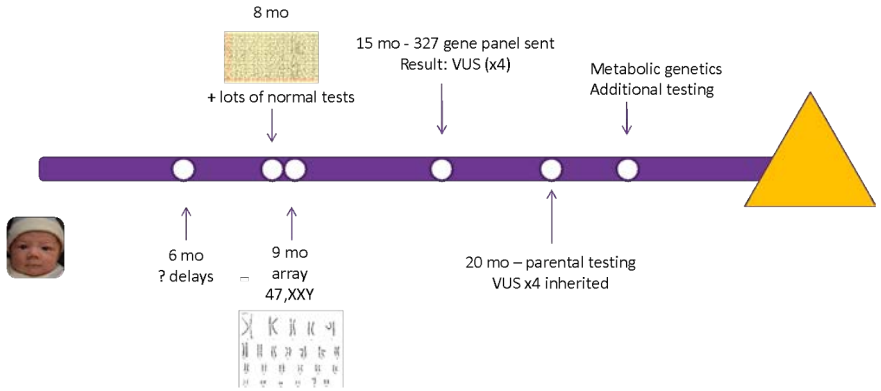


Only a speed bump!





So what's next?



Engage genetics MD / genetic counselor

Follow up and review testing to date

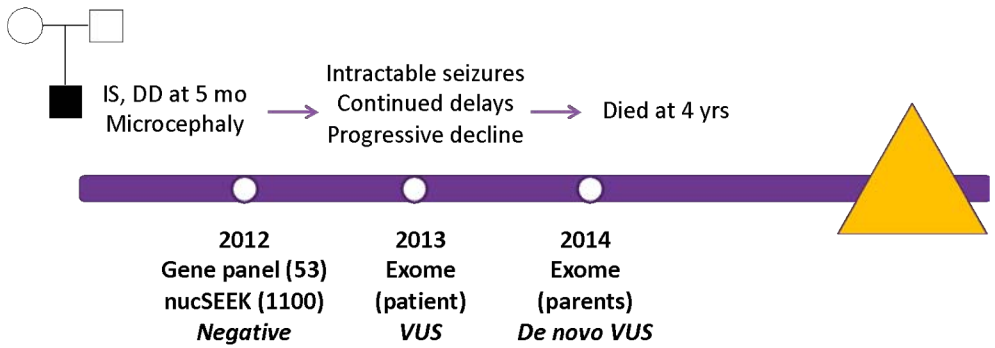
- Are new tests available?
- Is there new clinical or family information?
- Timeline: 1yr…?

Ask for reanalysis

- Exome can be reanalyzed to incorporate new information

Consider research

Uncertainty



Ask the experts

- Is anyone studying the (uncertain) gene?
- Use ‘matchmaking’ databases

Follow up and review testing to date

- Are new tests available?
- Is there new clinical or family information?

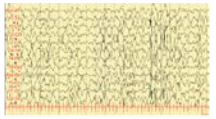
Ask for reanalysis

- Exome can be reanalyzed (after >1yr)

Consider research

Nevertheless…the geneticist persisted!

8 mo



+ lots of normal tests

15 mo - 327 gene panel sent
Result: VUS (x4)

Metabolic genetics
Additional testing
(Nondiagnostic)

6 mo
? delays
